Express, they are SLIMs. If you take a released SLIM-PWB and convert it to another CAD design for some other PWB house to manufacture, it will be a SLIM, but only if the conversion is 100% accurate. Any change to the pwb design negates its status as a "released SLIM".

The links to the pictures contains a comma after jpg.

I have corrected the links

http://www.qsl.net/bg6khc/closure.jpg

http://www.qsl.net/bg6khc/closure1.jpg

http://www.qsl.net/bg6khc/closure2.jpg

Nice looking enclosures..

Hi Stephen,

My view on IC sockets is:
When IC sockets are added you are adding an extra mechanical connection. In theory mechanical devices are not as reliable as low voltage ICs. If you must use IC sockets as in computer mother boards for BIOS chips. Then I would use turned pin gas-less IC sockets. The IC is harder to push into the socket because the oxide coating is scraped off the IC pins. A gas-less connection is formed between the pin and socket and shouldn't oxide as air can't in get between the pin and socket. I would never use the cheap pressed tin sockets as they will oxide in no time. I've heard of stories where the Maintenance technician went around wiggling all the ICs in their sockets to get it working again.

My rule is: (1) Don't use sockets unless you have to. (2) If you must use sockets, then use only gas-less pin sockets.

Has anyone else had this experience?

Hi. I have a question you might be able to help me with. I was thinking of adding IC sockets for U1-U4 for the control board do you think this give me any problems? I will be using gold contacts.
Any help would be apreciated, thanks in advance Stephen.

Rodrick,

This is all good. But on my bench, things are never that controlled.

In fact, about a month ago I managed to fry about 1/2 the 17 chip IC content of a board I built that has a bunch of Af related filtering functions on it. There was an LCD module on a bracket on the bottom of the unit and somehow a 1/4" jack that normally plugs into my rig worked its way through a very small opening and managed to touch just the right thing on the back of that LCD to cause the "fry event" to occur.

Maybe other guys are a lot more careful and lucky. But here, Mr. Murphy lays in wait – sometimes I feel he's on a personal mission to kill every home-brew gadget I've cooked up... Other guys may have better luck. The reliability issues associated with using sockets are really minimal compared to the damage I can do to a PCB pulling a IC off. And sockets can make it real easy if you are unsure which IC has failed (or been fried).

So a long time ago, after having lots of bad luck like this, I have made sockets part of my SOP for everything unless it's going to have an RF related impact. That is a very significant concern on the SSA, however.

Good luck!

Hi Jeff,

As I've indicated these are my views on sockets. I would rather troubleshoot and unsolder 8 ICs than adding 17 sockets just in case I blow them up. And knowing that I have a more reliable finished product when finished. As I've indicated, if I ever use IC socket I use gas-less sockets.

There certainly are reliability issues with sockets, though probably no more so than with the header pin connections. As there are only four latch ICs,it would be no great expense to use quality sockets, so if you use sockets you should certainly use good ones.

If you take a released SLIM-PWB and have several made by Express, they are SLIMs. If you take a released SLIM-PWB and convert it to another CAD design for some other PWB house to manufacture, it will be a SLIM, but only if the conversion is 100% accurate. Any change to the pwb design negates its status as a "released SLIM".

> > but there are a few things that make me wary. The PLO boards have the two outputs fairly close together, which may reduce the isolation. They also have the PLL reference clock connector located far from the PLL chip, increasing the odds of interference between the clock and the outputs. Likewise with the clock on the DDS; I recall that Scotty discovered that some spurs are reduced if you put the DDS clock input as close as possible to the pin, which means you can't use a connector with legs. The SMA connectors on the PLO and several other boards are very close to the edge, which might hamper fencing, and depending on your mounting arrangement might cause connectors on one board to be very close to those on another board. The bottom of the boards is not shown, but hopefully has no solder mask, to facilitate fencing and attachment of coax or connectors. Many of the boards have mounting holes, which you would likely have to cover up to use the normal mounting methods.
> >
> > Several of the boards, like the mixers, probably need more top ground plane to preserve isolation. I'm not a big fan of putting ground pour everywhere, but in some places it is necessary. Where fencing is needed in the middle of the board, such as the DDS, the ground plane to which it solders should be free of solder mask.

Thank you for the help. I couldn't think of any problems it could create as long as I used gold type IC sockets.

Hi All,
 Just a quick comment about "zapping" the 74ACT573 buffer I.C.
 I zapped one by shorting its output to ground. According to the mfg specs, this amount of current should not hurt the chip (BS). This was not a total zap, it did not totally die. The chip responded "almost" normally after the short.
 After the short occurred, the MSA would sometimes command to the wrong frequency. I traced the problem down to that IC output and found that its trailing edge (1 to 0) fall time had increased substantially. So, while its output signal was falling, other coupled lines created "glitches" on that output. In my opinion, the output impedance is what really changed (sink current), allowing "normal" line crosstalk to interfere with the output signal. The other 7 outputs worked perfectly.
 The bottom line to all this: shorting the buffer output may not result in a hard failure, but might introduce other weird soft failures. So, be careful about dropping stuff into your MSA with power on (like I did).
 Scotty

I used to put everything in sockets. Not any more. Over time I have had more problems with the sockets causing problems than anything else. And do not use gold sockets, if the pins of the IC's are not gold plated, not many of them any more. Same reason they do not recommend mixing the tin plated pins with gold plated contacts.

I remember having to fix old ITT word processors. We took the cards out which were all wire wrapped, layed them on the floor and stepped on them to push all the IC's back down into their gold plated sockets. Fixed 95% of the problems with the old beasts. Go find a board that has had an IC in a socket for a while, and push down on the chip. It moves, you can push it back down, repeat in one month and the IC will have ridden up a bit again. Given enough time the contact will be broken.

The faster the electronics get the more problems the sockets seem to introduce also, so keep that in mind.

I would recommend you buy a good de-soldering station. I have a cheap one from circuit specialists, and it is some of the best money I have spent on my workbench. Makes quick work out of having to change an IC, or any other thing on the board.

Dale

8062. SLIM PCB Boards listed on ebay. Lot of 16 new

Yahoo group: spectrumanalyzer (2011)
Date: 2011-05-16 06:01:16 UTC
From: vna4sale
Topic: 8062 Message: 8062

A friend of mine just listed a lot of 16 PCB boards on ebay for sale (item number 180667798772) if anyone needs them to get their spectrum analyzer started. They bought 2 sets and these are the extras.

The listing is here: http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=180667798772

Also see Mini-Circuits listing from the same seller for the complete MiniCircuits kit unused. They will probably be auctioning off the built project in the next few days as well so stay tuned to that seller.

True,

But he tells about what's not working and++

On his ebay shop, you'll find a bag of MiniCircuits parts on acution.

If it wherent for he abysmal shipping rates to Euroland, I'd gone for it
myself!

From: Steve
Topic: 8068 Message: 8068

Scotty,

With respect to the crystal ladder filter board PWB-CLF-5, did you intend that the crystal case be soldered to the bottom side of the PWB?

Thanks.

Steve

Hi Steve,
 Yes. Soldering crystal cans to ground is "standard operating procedure" when building crystal filters.

I did that on the amplifilter, but had a heck of a time getting the solder to stick to the can. Finally applied flux with a flux pen. Probably would have helped to use emery cloth on the can before installing.

I would not solder near the bottom of the crystal can
for a solder sealed crystal. The atmosphere inside the
can is very very dry and any leaks around the solder
seal will allow moisture in over time. We are talking
microscopic pin holes here.

I have had to deal with this problem for years because
of the crystals used in King and Cessna aircraft radios
that were solder sealed. The failure mode of a crystal
with a leaky seal is strange, not sure what it would do
to a filter crystal but it cant be good.

If you want to ground the can of a solder sealed crystal
attach the ground at the top away from the seal area.

In my experience resistance weld crystals dont have
any appreciable leakage problems in the manner of
the solder sealed ones.

hi,

I find that the USB2LPT (http://www-user.tu-chemnitz.de/~heha/bastelecke/Rund%20um%20den%20PC/USB2LPT/index.html.en) is not compatible with the layout of the slim_cb_nv.

The first pin (1th pin) of USB2LPT is just the 13th pin of the slim_cb_nv board. Anyone can give me some idea ?

my test: http://www.qsl.net/bg6khc/test_slim_cn_nv.htm

Thanks
BG6KHC

I believe your USB2LPT is simulating a parallel port card, which has the 25 pin female connector. You need a standard Parallel Port cable, which has a 25 pin Male connector on each end.
 If your testing works, you could design a pwb with two 25 pin Male connectors to replace the parallel port cable.
Scotty

A db25 pin converter PCB board has been designed and sent to a PWB house. (pic: http://www.qsl.net/bg6khc/test_slim_cn_nv.htm).

However, I'm really worry about "run into a lot of odd issues".

I would wait for Scotty to publish a final version of this USB adaptor/control board.A parallel CB now is good enough for me to test my MSA.

It has been stated many times on this group that a standard parallel to USB adaptor that can be bought from various sources will NOT work in this application.

You will need to build a dedicated unit such as the one designed by G8KBB the details of which can be found on this group , look under the FILES section, USB controller.

This is a proven design which many users have built and used with another VNA.

8078. Relays 75 ohm

Yahoo group: spectrumanalyzer (2011)
Date: 2011-05-22 02:17:22 UTC
From: Steve
Topic: 8078 Message: 8078

I saw some HP 8765A OPT 015 coaxial relays today in the flea market at the Dayton Hamvention. The HP datasheet <http://www.home.agilent.com/agilent/redirector.jspx?action=ref&cname=AGILENT_EDITORIAL&ckey=1000030385%3Aepsg%3Adow&lc=eng&cc=US&nfr=-11143.0.00&pselect=SR.GENERAL> lists the relay impedance as 75 ohms, 55mH.

I do not know what to make of the 55mH part of that spec, but the 75 ohms is obviously different from the 50 ohm RF paths in the MSA.

What would be the effect of using these relays for the the 1G-2G-3G switching? Big problem? Little problem? Somewhere in between?

Thanks.

From: Sam
Topic: 8078 Message: 8079

75 ohms is no problem. Because of the short signal path through the relay, the effect is minor at 10.7 MHz, and is probably negligible compared to the non-50-ohm output impedance of Mixer 2. There might be a tiny effect on signal strength, but whatever it is would be accounted for in path and frequency calibration, along with mixer losses, etc.

The 75 Ohm, 55 mH specification is the solenoid resistance and inductance, not the RF path impedance.

If nobody has a spare, you might consider ordering a set of 3 Miniboards from ExpressPCB for about $60. Three amplifilters fit on one board so you would have a total of 9. If a few others are also interested, you could end up with a board for a decent price.

Another option, if you're feeling adventurous, is to try a clone I made of the amplifier design that is compatible with other board houses. You could get one for about $15 from BatchPCB. There are other options as well. Keeping in mind that it wouldn't be a "Released SLIM", using Scotty's nomenclature for variant designs.

The amplifilter isn't actually an "official SLIM" anyway. It is slightly smaller than the double-SLIM size. I figured that if anyone wanted to make it SLIM size, they could easily pad it. Will, have you actually constructed the amplifilter with your board?

No, I haven't yet.

That would by the reason behind the "adventurous" qualifier.

Thanks Geoff.

I have completed the test of my version's slim_cb_nv with USB2LPT along with slim_adc16 and slim_logdet by using Ver115 test program.

It seems that no odd issues encountered.

I have updated the test results on my website:

http://www.qsl.net/bg6khc/test_slim_cn_nv.htm

http://www.qsl.net/bg6khc/test_slim_logdet_and_adc16.htm

Thanks.

Thanks for the offer, Will, but I am still hoping that someone has a spare. After all, they are always ordered in 3s!
If I can't get one, then I will have a go at transferring it into another package myself. My biggest problem with getting PCBs made is the cost most companies charge for shipping to the UK (ExpressPCB want $50 for shipping!). I have seen several Chinese companies on Ebay offereing a low cost service (and a reasonable $15 shipping cost). Anyone have any experience or comments on these?

No, I haven't yet.

That would by the reason behind the "adventurous" qualifier.

There's a company called "iTead" that offers a somewhat unique service. They have 10 boards smaller than 5cm by 5cm for $12.

However, there are some caveats. I don't know how many people know about Dave Jones of EEVBlog, but he tried them out:

http://www.eevblog.com/2011/03/11/eevblog-155-itead-studio-pcb-prototype-goof/

The real issue he faced was the minimum trace/space sizes. None of the SLIM boards would have this issue.

I have just had a look at the iTead web site and their prices are truly incredible! They currently have an offer for 10 off, 5cm * 5cm double sided PCBs for $9.90 for all 10! Don't know about the delivery costs yet, but they despatch from China via air mail which isn't usually too expensive, but a bit slow (compared with UPS and FedEx, anyway).
I watched the Dave Jones video and note the issue with 6mil/6mil track width/spacing but it looks like everything would be OK at 8mil and above. I don't image this will be a problem with any of the SLIM designs.
It's a shame that their standard sizes of 5cm * 5cm or 10cm * 10cm ($24.90 for 10) don't fit the SLIM sizes very well, but at the price I shouldn't complain. The only issue I can see is that they state "Single design, no panelizing" and so I guess that means that I can't put several SLIMS on one 10cm * 10cm board. I would need to shrink the PCB for the amlifilter by about 5mm to make it fit within 5cm * 5cm, but that looks quite possible without changing the design significantly.
I think I will try to convert the amlifilter to Eagle format and give them a go. I will report back to the group how I get on, but don't hold your breath - I'm a novice with Eagle!

The iTead prices are generally good, but it is inefficient to have to use a 5x5 cm board to get a single SLIM (approx. 3x3 cm). But in the case of the amplifilter, a simple redesign could shorten it so it would fit into a 5x5 cm board. The impedance matching at each end uses two trimmer caps, each in parallel with a fixed cap. The trimmers could be omitted; they are completely unnecessary. Likewise, two series inductors are allowed, so you can get closer to the desired value, but that is also unnecessary, so one of the inductors could be omitted. I ended up jumpering over the impedance matching at one end, and using fixed components at the other end. It turned out that it wasn't really necessary to do impedance matching, but one impedance matching circuit is still useful to provide a low-pass filter, whose component values aren't all that critical.

On the 6/6 issue: I don't think I have ever used a trace narrower than 10 mils on an MSA board, and the default clearance around pads and traces in ExpressPCB is 12 mils, so there is no need to push anywhere close to the iTead 6/6 limit. (The narrowest trace on the amplifilter board is probably 15 mils.)

8093. Cavity filter polishing?

Yahoo group: spectrumanalyzer (2011)
Date: 2011-05-25 05:29:35 UTC
From: William Dillon
Topic: 8093 Message: 8093

I have to admit I feel like this is a stupid question, but I have to ask. Is it vital that the inside of the cavity filter be polished? Is there some kind of electron cloud that forms inside that must be able to conduct with the walls of the pipe? I finished a filter and it doesn't work at all. Then I thought about other peoples filters and the silver plating and thought "why would they do that unless the inside surface had to be extra-conducitve to the inside air. Is it likely that this is the reason mine doesn't work?

Thanks!
- Will

Sometimes it's the way you tune it e.g. I started with the last cavity screw and worked towards the input.
You can't do much wrong here, maybe with a wider bw or insertion loss, unless you have a short or open connection.

From: Sam
Topic: 8093 Message: 8096

If you don't have an actual bad connection or shorting problem (maybe with a coupling loop or with a tuning screw touching the center pipe), you should be able to get some kind of response even with various types of defects, and the shininess of the insides is not a factor.

Current flows up and down the resonators and up and down the cavity walls, interacting magnetically with the coupling loops. The tuning screws add a little capacitance to the end of the resonators, which has the same effect as altering their length. Due to skin effect, the current in the cavity is very near the surface of the copper. I have read statements to the effect that in an oxidized cavity you are forcing the current through the high-resistance oxide because the oxide constitutes the surface. However, skin-depth calculations take resistance into account, and a thin high-resistance coating does not affect the current flow in the underlying copper. (A thick layer would create some dielectric loss that would affect the Q of the cavity, but would not prevent it from working.)

For the heck of it, I filled a cavity with polyurethane foam. The cavity still worked, with lower Q. Overall, it was a disaster because when you heat the cavity to put the top on, the foam wants to expand again.

The issue may be tuning. If the cavities are not tuned to approximately the same frequency, you may not get any response. If all your center resonators are the same length, and all your tuning screws are set to the same depth (and don't touch the resonator), then you should have a decent starting point for tuning and you should see some response. If the resonators are not the same length (measured from the open end of the resonator to the inside bottom of the cavity), it may take some trial and error tuning to get the frequencies close enough to see a response. (Even if you cut the resonators to equal lengths, they may have different lengths projecting inside the cavity.)

Thanks to everyone that has responded so far. I'm working on building a new filter to hopefully rule out some building deficiencies. I certainly learned a lot about the building process with the first filter. When I hooked it up to the analyzer, it looked exactly the same as an open connection. I thought there was some kind of lacquer coating on the inside of plumbing pipes, but I guess not, and from what it sounds like it wouldn't matter anyway.

Thanks again,
- Will

> If you don't have an actual bad connection or shorting problem (maybe with a coupling loop or with a tuning screw touching the center pipe), you should be able to get some kind of response even with various types of defects, and the shininess of the insides is not a factor.
>
> Current flows up and down the resonators and up and down the cavity walls, interacting magnetically with the coupling loops. The tuning screws add a little capacitance to the end of the resonators, which has the same effect as altering their length. Due to skin effect, the current in the cavity is very near the surface of the copper. I have read statements to the effect that in an oxidized cavity you are forcing the current through the high-resistance oxide because the oxide constitutes the surface. However, skin-depth calculations take resistance into account, and a thin high-resistance coating does not affect the current flow in the underlying copper. (A thick layer would create some dielectric loss that would affect the Q of the cavity, but would not prevent it from working.)
>
> For the heck of it, I filled a cavity with polyurethane foam. The cavity still worked, with lower Q. Overall, it was a disaster because when you heat the cavity to put the top on, the foam wants to expand again.
>
> The issue may be tuning. If the cavities are not tuned to approximately the same frequency, you may not get any response. If all your center resonators are the same length, and all your tuning screws are set to the same depth (and don't touch the resonator), then you should have a decent starting point for tuning and you should see some response. If the resonators are not the same length (measured from the open end of the resonator to the inside bottom of the cavity), it may take some trial and error tuning to get the frequencies close enough to see a response. (Even if you cut the resonators to equal lengths, they may have different lengths projecting inside the cavity.)

8098. Visual Guide

Yahoo group: spectrumanalyzer (2011)
Date: 2011-05-27 00:32:58 UTC
From: Sam
Topic: 8098 Message: 8098

I have posted a file called MSA_VisualGuide in the Files section. It is an attempt to explain the use of the MSA by presenting an overview of the main windows (main graph, Smith chart and Two-Port windows) and their menus and controls. It does not get into great detail on every use of the MSA--such as crystal analysis--but is intended to help the user find where to go to do what needs to be done. Let me know what you think.

8099. Active Return Bridge (ARB) RLC Offset Network for Impedance Measurements

Yahoo group: spectrumanalyzer (2011)
Date: 2011-05-27 12:22:00 UTC
From: lh1907
Topic: 8099 Message: 8099

The primary purpose of this post is to describe how the RLC Offset Network is used with Sam W's RL_To_Impedance spreadsheet to measure antenna impedance at HF. A homebrew HF receiver with 10.7 MHz (7 KHz BW) 1st IF was used to measure ARB response amplitudes.

Three more pics are uploaded to the Larry_W2HHV folder.

1. RLC_OffsetNetwork.JPG: This network is used to provide a series R+_jX offset control of impedance circle center position in RL_To_Impedance spreadsheet.

2. ActBridgeFixture.JPG: Shows the physical layout of the ARB, Buffer Amps, 10 dB attenuator interface to RLC_OffsetNetwork. The "To Zx" connector is connector to a 49.9 ohm load which is used to determine value of Calibrated Air Capacitor (Cvar) which resonates with selected switchable inductor. Knowing the series L value at measurement frequency, all other offset reactance values can be determined for any other Cvar setting.

3. Z_RL_Circles.bmp: The measurement conditions for the four impedance circles are:

a. 49.9 ohm load, LC Network at resonance - This measurement is used to calculate the inductance of select inductor(s) based on Cvar setting. Cvar=118.6pF; Both reactances = 132.9 ohms.

b. Series C - With LC Network connected to Zx and Series R=0, Cvar is adjusted to maximum Return Loss (RL) at some capacitor setting near mid range of Cvar. Zx generates the smallest impedance circle possible for the Zx value being measured. Cvar=314.8 pF, -jX = 50.1 ohms (Xoffset=+j82.8 ohms based on case a measurement);

c. Series C1 - Cvar is varied from the Series C setting (case b) to reduce RL by about 6 dB. Or use Cvar setting which reduces RL by the largest value possible below 6dB. Cvar=166.0pF, -jX = 94.95 ohms (Xoffset=+j37.95 ohms based on case a measurement); and

d. Series R/X - Return Cvar to min Zx value of case b. Insert series R value to reduce RL by about 6 dB. Or use series R which reduces RL by the largest value possible below 6dB. Series R = 53.2 ohms and Xoffset=+j82.8 ohms.

To summarize the measurement sequence.

1. Pick a stepped L value which results in the net reactance of series L/Cvar network being a conjugate match to Zx reactance (case b). This is maximum RL possible for Zx being measured.

2. Replace Zx with a 49.9 ohm load and adjust Cvar for max RL. L/Cvar reactances are equal at this series resonance condition. Calculate +jX value of L from know Cvar value. (case a above).

3. Reconnect Zx and adjust Cvar for about 6db reduction in maximum RL value (measurement 1).

4. Return Cvar to maximum RL condition (measurement 1) and insert series R for about 6db reduction in maximum RL value (measurement 1).

Measurements 1 and 3 are reactance offsets only and measurement 4 is a resistance and reactance offset measurement. By including the LC resonance impedance circle on Impedance Graph, the maximum resistance width and reactance height of impedance triangulation box for Zx measurement can be checked relative to ARB characteristics for measurement frequency (10.098 MHz).

Since I am using this ARB Fixture to measure the impedance of a one wavelength, 80 meter, horizontal loop antenna, I do not expect to measure any high impedances which involve adding a parallel R offset. The Cvar range (31 to 472 pF) and L range (2 to 30 uH in 2 uH steps) should be suffice to characterize this antenna over 3-30 MHz HF range. Self resonance frequency of parasitic inductance of LC Network is 50 MHz, so the "no L selected" condition should provide enough offset from the 2 uH L value to measure Zx at 10 meters. The Cvar min may not be low enough. Time will tell.

I used a QRP LC Network antenna tuner to match antenna using ARB at 10.098 MHz (RL = - 41.5 dB). This tuner has a calibrated air capacitor. I use the shunt network, to determine resonant C value at measurement frequency for the L value of match condition. Then, the L value was calculated. Using these LC match values, the Zx value was "reverse" calculated.

Results are:
QRP Tuner: Zx = 42 -J73.7 ohms
ARB Impedance Circles: Zx = 49 -j71 ohms

Larry,
Nicely done. I had forgotten about that spreadsheet. For those who haven't seen it, it allows you to measure impedance and related quantities using 3 measurements of Return Loss, one with the DUT alone, and the others with a resistor and then a capacitor in series with the DUT. In effect, it lets you measure both magnitude and phase with just a good return loss bridge; no VNA required. The three RL measurements each generate a circle of possible impedances, and the solution is where all three intersect. (Depending on the scaling of the graph, the circles may actually look like ellipses, but the intersect point is still the same.)

I noticed that the instructions in the spreadsheet refer to using a parallel resistor and capacitor, whereas the data entry boxes specify series R and C. I uploaded a corrected version to consistently refer to series components; it's on my website under Manual Return Loss Measurement. Larry, I see that you used series components, and you apparently also somewhat customized the spreadsheet and procedure. It appears to have worked well.

Hi Lin,
You are doing better than a 20 dB improvement. Your "with" trace is down in the mud and a good difference between the two traces cannot be made. However, I'm guessing you have about a 30 dB improvement. Good going.

Hi Lin,
Are you sure it really stopped running? On my computer, 10,000 steps requires about one minute before the sweep will start scanning. It takes time to calculate all the steps and put the commanding information into the software arrays.

You are right. I did not wait enough time. After I wait about 40 seconds, it is ready to sweep. Maybe we can put a reminder somewhere, if the number is above 5000.
Thanks

Lin,
The software does limit the number of steps, but the limit is huge--something like 40,000. I used a large number of steps to do a scan for spurs, and I had to let the scan run for hours. Even simple things like Redrawing the graph become painfully slow when you get beyond a few thousand steps. I typically run with 200-400 steps, and almost never need more than 1000.

I believe the size of calibration files is limited to 2000 steps because file processing becomes very slow above that. I have just now put in a warning if the number of steps is specified above that level. That will at least protect against someone accidentally adding an extra "0".

Yes, the isolation amp is extremely effective. I think I ended up with a 25 dB improvement. I highly recommend it to anyone who wants to use the MSA with the TG below 1 MHz.

8108. Re: Steps/sweep in V116 RevD

Yahoo group: spectrumanalyzer (2011)
Date: 2011-05-28 16:55:25 UTC
From: Greg Broburg
Topic: 8102 Message: 8108

Hello Sam;

this issue of having to scan 40000 steps seems to me
to be not necessary in light of the fact that most people
have added wider band IF filters. My suggestion early
on was to make one filter a pass through of the 10M7
and use only the bandwidth of the first IF filter. This would
allow about 2 MHz window. Yes, I understand that we could
cook up a precise 1M0 filter at 10M7 and this would be
very nice. Obviously it would be an LCR. Or if somebody
has another favorite IF that would make a nice 1M0 BW
then lets hear about it.

Anyway the IF BW seems to me to be the big issue for
wide sweeps. A full BW sweep that takes an hour is not
useful it seems to me.

I know I am asking for some argument here but this
wideband IF idea for faster wide sweeps is a well known
issue among the big boys.

Regards;

Greg

Once you find where the action is then you
can go back and whittle it down to small steps.

Hi Greg,
 Don't worry about arguments being raised. It is just the law of physics that sweep speed and resolution bandwidth are interdependent. For the MSA, the real sweep speed limitation is Liberty Basic. Back when I first chose LB as the software platform, computer processor speeds were less than 600 MHz and LPT bus speeds were 1 MHz. These determined the limitation of the MSA sweep speed.
 Well, times have changed and computer speeds are growing at an exponential rate. Now, the main speed limitation is the speed at which LB can "paint" the monitor. It is really a suckingly slow process that the LB programmers are not too concerned with. Their speed priorities are concentrated in other areas of their software. Their graphics probably have to go through several subprogram modules to finally get to the MicroSoft screen format.
 I'm no computer wizard, but that's my observation.

allow about 2 MHz window. Yes, I understand that we could

cook up a precise 1M0 filter at 10M7 and this would be

very nice. Obviously it would be an LCR. Or if somebody

has another favorite IF that would make a nice 1M0 BW

then lets hear about it.

Anyway the IF BW seems to me to be the big issue for

wide sweeps. A full BW sweep that takes an hour is not

useful it seems to me.

I know I am asking for some argument here but this

wideband IF idea for faster wide sweeps is a well known

issue among the big boys.

Regards;

Greg

Once you find where the action is then you

can go back and whittle it down to small steps.

On 5/28/2011 8:32 AM, Sam wrote:

Lin,

The software does limit the number of steps, but the limit is huge--something like 40,000. I used a large number of steps to do a scan for spurs, and I had to let the scan run for hours. Even simple things like Redrawing the graph become painfully slow when you get beyond a few thousand steps. I typically run with 200-400 steps, and almost never need more than 1000.

I believe the size of calibration files is limited to 2000 steps because file processing becomes very slow above that. I have just now put in a warning if the number of steps is specified above that level. That will at least protect against someone accidentally adding an extra "0".

True, there may be no need for 40000 steps when you have a wide RBW. Way back when I did that, I had only a narrow filter. And I used a strong video filter and lots of wait time because I was looking for spurs that were almost in the noise. That's why the scan took so long.

You certainly could make a 2 MHz or so RBW by having one path bypass the IF2 filters, but there may be some Mixer 2 products that you would want to get rid of.

It's a pretty simple matter to make a 400 kHz RBW with ceramic filters, which is what I am using for my widest filter. That would let you scan a 400 MHz range with roughly 1000 points. With no wait time added, that would probably take about 7 seconds on a mid-range PC.

For people like me who use the Expanded Log Detector, the RBW has to fit within the passband of the final noise filter, which complicates the use of very wide filters, since a very wide RBW would require even a wider noise filter.

While LB purports to have a compiler, it is really just a tokenizer so the final program runs through an interpreter. That is ultimately the source of the speed issues.

Hello Sam;

ok, so why not use two detectors, one fast detector and the expanded Log detector. the goal is to find signals with the fast detector and then to slow down the analysis to feed the expanded log detector when you find something. I know that there are issues if the signals are very small however in my experience looking for small signals means knowing where they are ahead of time so you can limit the sweep range to find the stuff that is buried in the noise.

The expanded log detector is not necessarily slow, it just is a step more complicated to give it a very wide bandwidth. Presently, I have a switched noise filter with two different filters; I would have to add a third of very wide bandwidth. Or, I would have to replace my current wide noise filter (about 1 MHz) with a wider one. That would not be hard, as the noise filter only needs to be about 30-40 dB deep. As a practical matter, though, I do mostly VNA work and my SA work is normally not wide-spectrum, so I'm good with 400 kHz as my widest filter. In fact, I don't have much use for a filter that wide. My main use for very wide spectrum SA would be examining a signal with harmonics, and you can easily show harmonics without using a large number of points.

But if someone can benefit from an ultra-wide RBW, it might be that a 2 MHz not-so-deep filter would do the trick, because the main objective would be to rely mostly on the cavity filter but reject any junk from Mixer 2.

8113. Harmonic mixing

Yahoo group: spectrumanalyzer (2011)
Date: 2011-05-28 23:45:55 UTC
From: Sam
Topic: 8113 Message: 8113

I was curious about how well the MSA could detect a very high frequency signal using harmonic mixing, so I bought a $25 "oscillator" on eBay that covered 5-6 GHz, or some such range. Unfortunately, I think it was actually a tunable filter, so I was out of luck.

If anyone has a stable high-frequency signal source, it would be interesting to see if the MSA can detect it. This would require figuring out what frequency to tune the MSA to such that a harmonic of LO1 would have the proper relationship to the signal. Even if there is a net 50 dB conversion loss at the signal frequency, there should be some usable range there.

Sam W.

Excellent idea Sam.

Now for my lost passion it would be nice to be able
to do with an RF analyzer what Bruel and Kjaer
did with audio analyzers many moons ago.

That is to be able to set up special sweep to
receive concepts such as to sweep the TG at the
usual programmed value and to sweep the analyzer
at 2F or 3F or 4F or 5F. Yes that means that at 5F
you will only get to 200 MHz as the top of the analysis.

Also, the idea of fixing the TG at one frequency and
sweeping the band up to 1G then to move the TG
and do it again in order to study the harmonic relationships.
B&K developed the concept of a Fourier Transform of the
recovered harmonics referred to as the Cepstrum
(Twisted spelling of Spectrum)

The mechanical analysis folks are using the Cepstrum
concept in some applications. You dont really know what
you can do until you see what comes back on the screen.

Best Regards;

Greg

From: taishan_ma
Topic: 8115 Message: 8115

Based on the comments, I have done some modifications on these boards, and some tests have also been performed.

I have put them here: http://www.qsl.net/bg6khc/my_version2.htm .

Anyone can give me some more advices? Thanks in advance.

From: inlinebeginner
Topic: 8116 Message: 8116

How accurate the MSA could be comparing to the commercial equipment?
Here is a 10.7MHz RBW filter test result comparison between MSA TG mode and HP8753ES

http://groups.yahoo.com/group/spectrumanalyzer/photos/album/608125393/pic/643419936/view?picmode=&mode=tn&order=ordinal&start=61&count=20&dir=asc

The two curves are almost the same above HP8753ES noise floor. However, below the HP8753ES noise floor, the MSA has better testability. This is because of its better noise floor.

Lin

Hi Lin,
 We couldn't ask for a better testimonial. I'm guessing your MSA's Resolution Filter is much narrower than the HP's.
 Your comparison really shows the accuracy of your Magnitude calibration. Well done!
Scotty

The two curves are almost the same above HP8753ES noise floor. However, below the HP8753ES noise floor, the MSA has better testability. This is because of its better noise floor.

What were the RBW settings for the two VNAs? I'm curious as to how much that created the better noise floor for the MSA, and how much was due to other factors.

MSA RBW 1kHz, HP8753ES RBW might be wider, I could not see the settings.

For what it's worth, I found an HP8753ES data sheet that specifies the typical noise level as -110 dBm, with a 10 Hz BW (that's Hz, not kHz). At 3 kHz BW, the max noise is specified as -82 dBm.

Assuming your MSA TG is -8 dBm, your noise level appears to be -110 dBm with a 1 KHz BW. So your MSA is matching the 8753's best, and your MSA bandwidth is 100 times what the 8753 requires to meet that noise level. My guess is that in this particular scan, the 8753 BW is 3 kHz, so it has 3 times your MSA BW but 30 times as much noise.

Sam
That is true, my MSA noise floor with 1kHz filter is -110dBm.
I think if I increase the power level on HP, I may get better result.
For the higher frequency, I post a new verification test result here:
http://groups.yahoo.com/group/spectrumanalyzer/photos/album/608125393/pic/1041862394/view?picmode=&mode=tn&order=ordinal&start=61&count=20&dir=asc

The bump arond 580MHz can be a little bit better (maybe 5dB) if I put 6dB attenuator both at TG output and SA input.I could not find why it has that problem.Maybe the TG driving level is too low or some reflection? My MSA RBW is 1kHz.

Hi Lin,
The very high MSA levels below 700 MHz are due to the high frequency products created in Mixer 3 (TG). If you place a low pass filter between the TG output and your UUT filter, those levels should be much lower. Try about a 900 MHz LPF.

That stuff between 500 and 700 MHz definitely should not be there. To some extent, it could be the result of high frequency signals in the TG, but I'm surprised it covers such a broad range. It is somewhat erratic, like noise, but doesn't seem erratic enough to actually be noise.

Try scanning 1-1000 MHz and see how things look at lower frequencies. Also try an uncalibrated scan of the TG to see how it looks (select None under menu Operating Cal->Reference To). That will show whether the TG loses power. Another way to check the TG is just to watch the scan that occurs while you do the Through calibration; that scan shows the raw TG response, which may have some waviness but should not have any dramatic dips.

Finally, if this is the result of >1GHz signals in the TG, you can eliminate it with a LPF on the TG.

The fact that the attenuators reduce the 580 MHz bump (but apparently not the area around the bump) suggests that the DUT has (1) some change in reflection of IF1 that comes out of MSA input or (2) some change in reflection of LO2 and/or LO3 coming out of the TG output. The LPF would also eliminate these effects.

Try the LPF first. I always run with a LPF unless I have a particular interest in the area close to 1 GHz. Note that in Transmission mode, calibration will automatically adjust for the TG dropoff caused by the LPF, but the weaker TG will reduce the dynamic range a bit. For your scan, the DUT response is high near 1 GHz, so the LPF will do no harm at all.

If you are in SA+TG mode, the declining TG will be superimposed on the DUT response unless you use a Reference line created with a Through scan and specify to subtract the Reference line from the data.

www.h-instruments.ecrater.com and www.h-instruments.ecrater.co.uk are selling cheap instruments and accessories.

8127. Cheap 2 layer prototype PCB boards - custom made

Yahoo group: spectrumanalyzer (2011)
Date: 2011-05-31 11:15:47 UTC
From: Electroniclab66
Topic: 8127 Message: 8127

Hi.
I found a producer of a cheap 2 layer pcb boards.
I did order for a project I was working on and the quality and service was very fine.
5 pcs of 2 layer board with silckscreen is 29.95$ for max size 50x50mm and 54.95$ for max size 100x100m. Both with free shipping.
See: www.h-instruments.com or www.h-instruments.ecrater.com (www.h-instruments.co.uk for UK)

Regards
John

8128. Re: MSA measurement fidelity

Yahoo group: spectrumanalyzer (2011)

From: inlinebeginner
Topic: 8116 Message: 8128

Scotty, Sam
The LPF solved the problem. Here is the result
http://groups.yahoo.com/group/spectrumanalyzer/photos/album/608125393/pic/1495660066/view?picmode=&mode=tn&order=ordinal&start=61&count=20&dir=asc

The reflection might be another reson, I put a 3dB attenuator between the DUT and LPF, it gets better.
Thanks
Lin

>
> Try the LPF first. I always run with a LPF unless I have a particular interest in the area close to 1 GHz. Note that in Transmission mode, calibration will automatically adjust for the TG dropoff caused by the LPF, but the weaker TG will reduce the dynamic range a bit. For your scan, the DUT response is high near 1 GHz, so the LPF will do no harm at all.

> >
> > That stuff between 500 and 700 MHz definitely should not be there. To some extent, it could be the result of high frequency signals in the TG, but I'm surprised it covers such a broad range. It is somewhat erratic, like noise, but doesn't seem erratic enough to actually be noise.
> >
> > Try scanning 1-1000 MHz and see how things look at lower frequencies. Also try an uncalibrated scan of the TG to see how it looks (select None under menu Operating Cal->Reference To). That will show whether the TG loses power. Another way to check the TG is just to watch the scan that occurs while you do the Through calibration; that scan shows the raw TG response, which may have some waviness but should not have any dramatic dips.

> >
> > The fact that the attenuators reduce the 580 MHz bump (but apparently not the area around the bump) suggests that the DUT has (1) some change in reflection of IF1 that comes out of MSA input or (2) some change in reflection of LO2 and/or LO3 coming out of the TG output. The LPF would also eliminate these effects.

> > > >
> > > > Assuming your MSA TG is -8 dBm, your noise level appears to be -110 dBm with a 1 KHz BW. So your MSA is matching the 8753's best, and your MSA bandwidth is 100 times what the 8753 requires to meet that noise level. My guess is that in this particular scan, the 8753 BW is 3 kHz, so it has 3 times your MSA BW but 30 times as much noise.

8129. Re: MSA measurement fidelity

Yahoo group: spectrumanalyzer (2011)
Date: 2011-06-01 14:24:19 UTC
From: Sam
Topic: 8116 Message: 8129

Wow, that was effective.

I notice that there is still some residual ripple along the skirt. That is likely caused either by calibration error (seems unlikely since your 10.7 MHz graph was fine) or by one of these reflection effects:
(Note the ripple is outside the passband, where the filter is probably very reflective at input and output).)
1. TG signal hits DUT, a large portion reflects back to TG output. If TG output has high return loss, this reflection is absorbed; otherwise some of it re-reflects back to the DUT, where some share of it will pass through and either increase or decrease the net transmitted signal, depending on the phase of the reflection compared to the original TG signal.
2. Transmitted signal reaches MSA input, some of it reflects back to the DUT, and most of that reflection is re-reflected back to the MSA input. This also increases or decreases the reading depending on phase.
3. In calibration with the Through, some of the TG signal reaching the MSA input reflects back to the TG output, and re-reflects to the MSA input, increasing or decreasing the reading.

In all these cases, the reading increases or decreases depending on the phase of some reflection, which means it varies over frequency and therefore creates ripple. Also, in all these cases, the potentially troublesome reflection gets absorbed before causing trouble if the TG output and MSA input have high return losses. That is most easily accomplished with attenuators or buffer amps. This issue would also be dealt with by using more elaborate calibration than simple Through calibration.

Enabling such calibration is high on the list of desired software features. In the meantime, attenuators and/or buffer amps are the way to go. In my design of the LO2 isolation amp, there are two amps on the board, and the second is used as a buffer amp for the TG, which solves part of this problem.

It would be interesting to see how the graph looks with 10 dB attenuators on each side. Of course, you would lose the very bottom of the response, but the skirt should be more linear.

Sam W.

8130. unpopulated DDS board

Yahoo group: spectrumanalyzer (2011)
Date: 2011-06-01 21:58:39 UTC
From: w4zcb77
Topic: 8130 Message: 8130

Anyone with a spare DDS board they want to donate or sell? Have friend, complete with a torn up DDS board that needs one to plant his 9851 on.

Advise on or off list.

Regards
W4ZCB

8133. cavity filter test

Yahoo group: spectrumanalyzer (2011)
Date: 2011-06-03 05:49:57 UTC
From: lbastetti
Topic: 8133 Message: 8133

Dear Group,

could please somebody post a picture of the MSA screen with the test of the cavity filter , as described at paragraph S of Integration and "Verification Test Procedure for the MSA,Modularized Spectrum Analyzer" page ?
I'm not sure of the result , had problem with one faulty MMIC , so PLO2 and PLO1 are still not closed in tin box , I would prefer verify the functionality also of cavity filter before closing the oscillators .
Is mandatory to box oscillators before this test ? I know there could be interaction between unshielded oscillators .
I've browsed pictures , there are many cavity filter photos, but not found any of this test .
My configuration is MSA+TR+VNA .

thanks a lot

Ladislao

8134. USB Support Status

Yahoo group: spectrumanalyzer (2011)
Date: 2011-06-03 17:53:10 UTC
From: Eric Nystrom
Topic: 8134 Message: 8134

I was reviewing the archives and was wondering what the current status of the USB support is? The last major discussion seems to have been Jan - Feb, with a mention (April) that it is supported in 116 beta.

I also saw a reference to an off the shelf Cypress board that has a CY68013A on it,
but did not see a part number for this board. Can someone provide the part number?

Eric Nystrom

There are a number of boards that would work. There isn't yet a SLIM "part number" for it.

But I will take this opportunity to mention that I had been working on a USB control board. It's been on the back burner for a while, but I thought maybe I'd use this post to link to the files to get people's opinions. The primary design criteria was to provide the same capability as the existing control board, but to separate each SLIM's connector. This would make the connectors going to the control board modular, just like the SLIMs. I don't like the inevitable rats nest that occurs with the current control board. Anyway, here they are:

http://alternet.us.com/wp-content/uploads/2011/06/USB-CB.zip

It bares noting that this is a very early draft. I'm bringing it to the group only to collect opinions.

It may look like a rats nest but it is a good way of reducing crosstalk on the digital control lines.

I sell a CY68013A board. It is not a Cypress board(I designed it). It is
the HSUSB board. All I/O pins are brought out to headers.
It is at <http://www.wb6dhw.com/For_Sale.html#HSUSB

The basic software is complete and works but I have been waiting to complete my own MSA in order to complete debugging.

It should run with any of the FX2LP boards. If you want to drive the current parallel port slim then you may use any of the chip options from the 56 pin upwards. If you want to replace the slim-cb then use a 100 or 133 pin version of the chip.

Completed drivers for the boards exist - there are two driver versions, one for driving slim-cb one for no slim-cb. All drivers have been signed by Ivan (thanks Ivan). Drivers are available for XP, Vista and Windows 7 in 32 and 64 bit versions.

The only programming needed is to put the 8 byte ID string into the eeprom on the usb controller. To do this, a program called 'usb configure' has been produced. Drivers are loaded dynamically evey time the board is plugged in so they do not need programming onto the hardware.

A DLL has been produced that interfaces between the hardware and the GUI application. This codes around limitations of liberty basic.

Code to drive the hardware has been added to the GUI.

If anyone wants to try it I have started to modify myVNA to drive the MSA hardware - a version that does (limited) spectrum analyser support is available but only drives the USB interface option. I will get back to this once I have working hardware of my own.

Dave

From: Sam
Topic: 8133 Message: 8141

I have posted a photo of my cavity filter test results in the SamW photo album. For some unknown reason, I get a small dimple at exactly 0 Hz when using small RBW, but it seems to be an artifact of this special test only, and does not appear in actual operation.

You can do a lot of testing without sealing the boards, but you may get extra spurs. I would recommend you at least put the side fencing in place; with 3/8" fence that projects a little below the board (so you can solder it to the bottom), it projects only about 1/4" above the top and does not get in the way of modifications. You may have to seal mixers 1 and 2 to get a good read on the ultimate attenuation of your cavity filter, to prevent through-the-air leakage from mixer 1 to mixer 2, but it may be sufficient to just tack the covers in place.

Hi Sam,
 That "dimple" you see at the center of the response (at "0" Hz) is an interference that I haven't quite figured out yet. It exists only during this test. Since we are more concerned with what the skirts look like, the "dimple" is just a nuisance.

I am not set up to test the USB interface, but I understand from others that it works if you use USB to control the MSA through the control board. If you want to control the MSA modules directly, bypassing the control board, the driver is set up to do so but (1) you need a board with a Cypress chip with enough pins to do this and (2) there may be an issue regarding the Cypress running at 3.3V and the MSA running at 5V logic. The latter issue may be related to the need to drive 5 clock lines from one Cypress bit, which maybe is too much load on 3.3V logic when the receiving logic threshold is 2.5V.

Hi all,

I have been running now on and off with pure USB interface.(no CB at all) I am preparing a detailed write up but in a nutshell this is my experience:

- The spectrumanalyzer software Version 116-4i commands the USB interface and I have not seen (or yet attempted to measure rather) any diffrernces with the CB. All the menu commands appear to work just fine. I am running everything on a Win 7-64 PC.. Dave Roberts wrote the USB code and provided drivers and utilities. And Sam Weterlin blended it into the spectrumanalyzer LB program.
Great job guys!

- Definitely you need the bigger Cypress 128-pin ICs because you need as a minimum four 8 bit ports for full functionality. The smaller Cypress IC don't have them.. Mine is a EZUSB FX2LP board that I got in EBay which includes a CY7C68013A 128-pin IC

. No soldering or any modification is requited. Unless you enjoy soldering 120-pi, closely spaced, this is the way to go.The board takes its power from the PC USB cable. Power for the SLIMs maybe derived from the CB or from Sam's power supply board (I use the later).

- I found that the CLK line gets overloaded by PLO3. I am working on a solution during this weekend.

- Finally: make sure that everything is working decently before you change over to USB: that way you can't blame the interface. I wasted a lot of time going back and forth because of this.

There are some finer points that i will be discussing in my forthcoming write up.

Hi Eric,

Yes, that's the one. I see that they have "more than 10" so i am going to order another one for myself to experiment on a different project.
With this board there is room for expansion to the MSA functionality. Don't get a 56 pin Cypress.

I thought my filter was out of tune and spent hours trying too minimize the dimple. Then I checked it with the "old" procedure and there was nothing wrong with it. I wish I had this info sooner....lol.
The dimple disappears when I place a attenuator at the input, reflections?

> (Note the ripple is outside the passband, where the filter is probably very reflective at input and output).)
> 1. TG signal hits DUT, a large portion reflects back to TG output. If TG output has high return loss, this reflection is absorbed; otherwise some of it re-reflects back to the DUT, where some share of it will pass through and either increase or decrease the net transmitted signal, depending on the phase of the reflection compared to the original TG signal.
> 2. Transmitted signal reaches MSA input, some of it reflects back to the DUT, and most of that reflection is re-reflected back to the MSA input. This also increases or decreases the reading depending on phase.
> 3. In calibration with the Through, some of the TG signal reaching the MSA input reflects back to the TG output, and re-reflects to the MSA input, increasing or decreasing the reading.
>
> In all these cases, the reading increases or decreases depending on the phase of some reflection, which means it varies over frequency and therefore creates ripple. Also, in all these cases, the potentially troublesome reflection gets absorbed before causing trouble if the TG output and MSA input have high return losses. That is most easily accomplished with attenuators or buffer amps. This issue would also be dealt with by using more elaborate calibration than simple Through calibration.
>
> Enabling such calibration is high on the list of desired software features. In the meantime, attenuators and/or buffer amps are the way to go. In my design of the LO2 isolation amp, there are two amps on the board, and the second is used as a buffer amp for the TG, which solves part of this problem.
>
> It would be interesting to see how the graph looks with 10 dB attenuators on each side. Of course, you would lose the very bottom of the response, but the skirt should be more linear.

From: william sprowls
Topic: 8133 Message: 8150

Hi Simon,
 I have not done any troubleshooting on this "weirdo" dimple. It occurs on my Original MSA but does not on the Verification MSA.
Since I don't have my lab anymore, my testing is quite limited.
Scotty

I thought my filter was out of tune and spent hours
trying too minimize the dimple. Then I checked it with the "old" procedure
and there was nothing wrong with it. I wish I had this info sooner....lol.

The dimple disappears when I place a attenuator at
the input, reflections?

Subject: [spectrumanalyzer] Re: cavity
filter test

I have posted a photo of my cavity filter test results in the SamW photo
album. For some unknown reason, I get a small dimple at exactly 0 Hz when
using small RBW, but it seems to be an artifact of this special test only, and
does not appear in actual operation.

You can do a lot of testing
without sealing the boards, but you may get extra spurs. I would recommend you
at least put the side fencing in place; with 3/8" fence that projects a little
below the board (so you can solder it to the bottom), it projects only about
1/4" above the top and does not get in the way of modifications. You may have
to seal mixers 1 and 2 to get a good read on the ultimate attenuation of your
cavity filter, to prevent through-the-air leakage from mixer 1 to mixer 2, but
it may be sufficient to just tack the covers in place.

Topic: 8116 Message: 8151

That seems to tame the ripple on the MSA response. Note that the same issues of return loss on the Tx and Rx ports probably exists for the HP.

> > 1. TG signal hits DUT, a large portion reflects back to TG output. If TG output has high return loss, this reflection is absorbed; otherwise some of it re-reflects back to the DUT, where some share of it will pass through and either increase or decrease the net transmitted signal, depending on the phase of the reflection compared to the original TG signal.
> > 2. Transmitted signal reaches MSA input, some of it reflects back to the DUT, and most of that reflection is re-reflected back to the MSA input. This also increases or decreases the reading depending on phase.
> > 3. In calibration with the Through, some of the TG signal reaching the MSA input reflects back to the TG output, and re-reflects to the MSA input, increasing or decreasing the reading.
> >
> > In all these cases, the reading increases or decreases depending on the phase of some reflection, which means it varies over frequency and therefore creates ripple. Also, in all these cases, the potentially troublesome reflection gets absorbed before causing trouble if the TG output and MSA input have high return losses. That is most easily accomplished with attenuators or buffer amps. This issue would also be dealt with by using more elaborate calibration than simple Through calibration.
> >
> > Enabling such calibration is high on the list of desired software features. In the

meantime, attenuators and/or buffer amps are the way to go. In my design of the LO2 isolation amp, there are two amps on the board, and the second is used as a buffer amp for the TG, which solves part of this problem.
> >
> > It would be interesting to see how the graph looks with 10 dB attenuators on each side. Of course, you would lose the very bottom of the response, but the skirt should be more linear.

For yet another approach...

I'm using a USB-to-parallel board copied from Dave Roberts' design (thanks Dave!), but have gone a slightly different direction on the code: I have it streaming commands out in 512-byte packets, including the delay commands, and receiving the data in a separate read stream. This gets around the latency problem with USB and the non-realtime nature of modern OSes, since the FX2 is now doing all critical timing.

The code is also all open-source and runs on Windows, Linux, and Mac OSX in wxPython. The FX2 code compiles with SDCC and downloads with cycfx2prog (Linux & Mac). I have the main-line VNA code running but have yet to port the rest of it. I'll post what I have so far if anyone's interested. My preference would be to put it up on SourceForge, using SVN for source control.

Hi Scott

It is not clear to me what latency you are referring to. With the current approach the only latency is the delay from asking the ADC to convert to getting the response in the next microframe - that you always have.

That having been said, I'm interested to see your approach. Also be very careful - you will find that the chip imposes a 64 byte packet limit for usb 1.1 interfaces.

Dave

1. it gets split over two subframes

Hi Dave,

That latency has actually mostly disappeared since fixing a read-timeout bug, so yes, it's small compared to the PLL-settling delay. Anyway, I'll post what I have.

8155. ADC output buffer transistor for USB

Yahoo group: spectrumanalyzer (2011)
Date: 2011-06-07 22:58:00 UTC
From: jghbeta
Topic: 8155 Message: 8155

Scotty,

Although not shown in the ADC schematic, the original configuration with the MUN2211 transistor had a pull up resistor at the parallel port pin.
The Cypress ports PA4 and PA5 which are the recipients of the ADC output transistors (now 2N7002) are limited to 10 mA and a maximum voltage of 5.25V.
Shouldn't we have a 500 ohm resistor from the gate to +5 Vcc and take the gate output to the ports?

It appears that the only Python versions are Python 2.7.1 and Python 3.2. Python 2.5 is not even mentioned in the sourceforge web site.

8159. Re: [spectrumanalyzer] ADC output buffer transistor for USB

Yahoo group: spectrumanalyzer (2011)
Date: 2011-06-08 12:44:16 UTC
From: william sprowls
Topic: 8155 Message: 8159

Hi Jim,
The reason the buffers are there is because the ADC chip cannot drive the parallel port directly. They are speced at only +/- 500 ua max.
  The Cypress chip could handle the direct output of the ADC (without a buffer), but would require a large software change.

Scotty,

Although not shown in the ADC schematic, the original configuration with the MUN2211 transistor had a pull up resistor at the parallel port pin.

The Cypress ports PA4 and PA5 which are the recipients of the ADC output transistors (now 2N7002) are limited to 10 mA and a maximum voltage of 5.25V.

Shouldn't we have a 500 ohm resistor from the gate to +5 Vcc and take the gate output to the ports?

I have an SPDT board that was included on one of the recent group buy boards, but I have not built it yet. It is a simple combination of three PE4251 switches to provide high isolation. Super-high isolation actually is not necessary if you provide filtering at the MSA input to modestly reduce out-of-band signals, so you could also get by with a cheap relay such as one of the HF3 relays. The 12V version draws a relatively small amount of current so it is not necessary to use a latching relay.

Sorry about that-- they've updated it. The current 2.5 with a Windows release is 2.5.4, so go to:

http://www.python.org/download/releases/2.5.4

And get Python-2.5.4.msi. Also fixed the numpy location and updated msapy.py, now version 0.0.2.

Sam,

Do you know where the PE4251 can be obtained? Digikey is out of stock on those.

Hi Scotty,
Sorry I did not make myself clear. I am not referring to the need for the buffers , but to the actual hardware implementation of their output when using the USB Cypress chip. With the tradional parallel port there is a pull up resistor but this is not the case with the Cypress port. I was seeking for confirmation that I should add a pull up ressitor then.

I should add that the PE4251 has an unusual feature--a square pad in the center of the IC bottom. That has to be soldered to ground. On my board, there is a large hole under the IC, so you can solder from the bottom. It works best if you first stuff the hole with solder paste, which will assure that the solder adheres to all necessary surfaces.
Conceivably you can do the soldering by applying solder paste and then heating from the top (soldering iron or hot air), but it is difficult to tell whether or not that is working.

I think it is the grounded pad that accounts for the amazingly good isolation.

Hi Jim,
 David has implemented the SLIM-ADC Module with his USB chip without a pull-up. He can correct me on this, but you may be able to "tell" the USB chip to turn on an internal pull-up on a port that is commanded to be an input.

Apologies - I may have forgotten to document it.

I put a 1K pullup on the buffer chip output

Dave,
Just so I understand it: the two input ports, PA4 (phase) and PA5 (magnitude), which receive data from the ADC buffer transistors should have about 3.3 volts in the absence of any signal. I measure 0.040 volts for the phase port and 2.2 for the amplitude.

I have some other not related issues which mask the response and make a more thorough testing difficult: It appears that the 5 dataclk lines are overloading PB0 and I cannot run PLO1 and PLO3 together until I resolve that. In spite of that, I tried adding a 10K a pullup resistor to 5 volts to the magnitude buffer transistor (which theoretically should be in parallel with the PA5 port pullup) and the "responsiveness" improved (for example I could see the effect of the video filters on the noise which I couldn't see before). Since the Cypress chip specs says that an input port will take up to 5.5 volts, the pullup to 5V should be OK and is easier to implement than doing it to 3.3V.

I still owe you a response on the issue of running the USB port through a hub. It is working fine directly attached to the PC so I am trying to resolve the other issues above first.

Hi Jim

Sorry for the delay - not got much access to computer at the moment.

Pull-ups to 3.3V and those voltages are fine. Equally a pullup to 5V would as you say work just as well as the ports are 5V tolerant. Given your report I'd probably agree and recomment a pullup to 5V.

On loading, you probably have more experience here than I do since I did not have a fully configured MSA when doing the development. Sounds, like I think Sam or Scotty said, that a buffer would be a good idea

From: jghbeta
Topic: 8171 Message: 8171

I have someform of oscillation/ high noise that extends from 0 to about 140 MHz. No signal gets thru even the zero hump disappears. beyond that, there is no noise and I getbnice, sharp clear signals. I just have the MSA running. Any ideas?

This site has become so quiet lately...

Hi Jim

I had exactly the same problem. I bet you are using the adf4112 or adf4113 chip rather than the LMX2326. The adf411X chips seem to default to a higher output current than the LMX 2326 which increases the loop gain causing instability. There was a bug in earlier versions of the software that did not take account of this but I believe that current versions are OK so long as you have the ADF4112 set in the configuration settings.

If you need more information or help let me know and I will tell you what to check.

Mark

Subject: [spectrumanalyzer] MSA oscillation

I have someform of oscillation/ high noise that extends from 0 to about 140 MHz. No signal gets thru even the zero hump disappears. beyond that, there is no noise and I getbnice, sharp clear signals. I just have the MSA running. Any ideas?

This site has become so quiet lately...

All of the beta software versions (which are all version 116-xx) have the necessary software fix for the ADF4112,3 and should work if you use the 4.7k current-setting resistor and specify the ADF4112 chip in the Configuration Manager.

In the more recent beta versions, there is a misleading instruction in the Configuration Manager:
"For ADF411x, specify 2326"

This was supposed to apply only to the ADF4118 and should read:
"For ADF4118, specify 2326"

There is a specific list entry for specifying the 4112, which also applies for the 4113.

Hi Sam,
Did the changes introcuced in Create4112initBuffer for the CB version made
it to the cb=3 (usb section) of the routine?

From: william sprowls
Topic: 8171 Message: 8176

Hi Jim,
 If you are using Version 115 (and) using it with Liberty Basic, you can just change the code. Go and find the following code:

```
[Command4112R]'needed:
rcounter,preselector,phasepolarity,control,Jcontrol,port,LEPLL,contclear ; commands AD4112
rcounter
  '[Create4112InitBuffer]'needed:preselector,phasepolarity
    N23=1     'N24,23 prescaler: 0=8, 1=16, 2=32, 3=64
    N22=0     'preselector defaulted to 32
    if preselector =8 then N23=0:N22=0
    if preselector =16 then N23=0:N22=1
    if preselector =64 then N23=1:N22=1
    N21=0     'Power Down Mode, 0=async, 1=sync  use 0
    N20=1     'N22,21,20 Phase Current for Set 2
    N19=1     'current= min current + min current*bit value
    N18=1     'use bit value of 7 and 4.7 Kohm for 5.0 ma
    N17=1     'N18,17,16 Phase Current for Set 1
    N16=1     'current= min current + min current*bit value
    N15=1     'use bit value of 7 and 4.7 Kohm for 5.0 ma
```

in the above code, change N15 thru N20 to the following:

```
        N20=0     'N20,19,18 Phase Current for Set 2            '12-3-10
        N19=0     'current= min current + min current*bit value '12-3-10
        N18=1     'use bit value of 1 and 4.7 Kohm for 1.25 ma  '12-3-10
        N17=0     'N17,16,15 Phase Current for Set 1            '12-3-10
        N16=0     'current= min current + min current*bit value '12-3-10
        N15=1     'use bit value of 1 and 4.7 Kohm for 1.25 ma  '12-3-10
```

What this does is change the PLL charge pump current from 5 ma to 1.25 ma. In very early MSA designs, the 5 ma worked very well using the National Semi PLL chip, LMX2325. I was never able to test using the ADF4112 series. I just "assumed" it would be ok. Guess not!!!!!

I believe now that this maybe strictly a USB issue. My understanding is that Dave completed his coding around end August 2010, therefore, any changes after that may have not been made their way to the USB code in Liberty Basic.
Sam maybe able to shed some light onto this.

8178. VNA reflection mode questions for V116_4i_beta

Yahoo group: spectrumanalyzer (2011)
Date: 2011-06-18 15:58:51 UTC
From: inlinebeginner
Topic: 8178 Message: 8178

Sam
I put a photo here:
http://groups.yahoo.com/group/spectrumanalyzer/photos/album/608125393/pic/1752124177/view?picmode=&mode=tn&order=ordinal&start=61&count=20&dir=asc

1) I did OSL cal, and meausred a 83 ohm resistor, the calculated S11 is -6dB, while measured -12dB. I use ZEDC-15-2B, Minicircuit DC.
2) The curve has glitches, is that because I did not do a phase cal?
3) The curve color looks like not matching the scale color.
Thanks
Lin

Dave's code was all transferred to my program file, so we don't have a USB branch and a non-USB branch. Scotty's change for the ADF4112 was made about the same time, and both were included in the original beta release of Version 116, Rev. A. So the ADF4112 changes are in all the beta releases through the most recent, which is Rev. D.

I understand and I see that there is a single branch of code, which is the way to go. However, I see that Scotty's mods are dated December 2010 whereas the USB code sections appear to be written earlier in August (although they may have been transcribed unchanged to the program at a later date).

I think my calculation was wrong, the return loss should be -12dB for a 83 ohm resistor load.

Topic: 8171 Message: 8182

The dates of the two changes aren't exactly the same, but they were both incorporated into version 116 Rev. A before it was released.

In the next version, the PLL listings will be clearer. There will be an entry for "2326,4118" and another for "4112,4113". (Internally, the software still codes these as simply 2326 and 4112.)

For the present, you should be sure you have selected "4112".

By not having done phase cal, do you mean you haven't calibrated the PDM inversion? That could definitely distort the measurement. I also note that your wait time is 0, which rarely gives good results in Reflection mode. Any glitch that occurs during the O, S or L calibrations will show up in every subsequent measurement, along with any glitch that arises in the measurement itself. Use Auto Wait or at least 20 ms wait time even for the wide video filter.

The color of very thin lines on a sharply contrasting background is not accurate on some monitors, and also gets distorted in jpegs. For compression, it is better to use .png files, which are accurate and are also very compact when the picture contains broad areas of flat color. (.tif files are good too, but I don't think Yahoo lets you upload them.) When I do use jpegs, I have gotten best results by using a dark brown rather than black background (to reduce the contrast), and using double-width graph lines.

On closer look, it appears that the graph colors are not simply distorted, but rather the phase and magnitude appear to be reversed. Try adding a marker to confirm which line is which. Is it possible your OSL cal was done incorrectly, such as reversing the O and S standards? Also, when you use a directional coupler as a bridge, be sure you hook it up in "reverse"--i.e. TG output goes to DC "out", DUT is connected to DC "in" and MSA input is connected to DC "CPL".

Sam
Thanks for the infor, I will try it soon. Before that I'd like to know how can I recall the OSL cal data from what I saved.

For the color, If you look at the curve and scale:
Scale Curve
Deg: Yellow Blue
Mag: Blue Yellow

When the Deg and Mag has a similar curve, you will read the blue curve and try to find the blue scale, and give us a wrong number. If we can make the color match like this:

Scale Curve
Deg: Blue Blue
Mag: Yellow Yellow

It may be easier to read the curve.

Thanks
Lin

For compression, it is better to use .png files, which are accurate and are also very compact when the picture contains broad areas of flat color. (.tif files are good too, but I don't think Yahoo lets you upload them.) When I do use jpegs, I have gotten best results by using a dark brown rather than black background (to reduce the contrast), and using double-width graph lines.

8187. Re: VNA reflection mode questions for V116_4i_beta

Yahoo group: spectrumanalyzer (2011)
Date: 2011-06-18 19:14:19 UTC
From: Sam
Topic: 8178 Message: 8187

The colors of the lines are supposed to match the color of the scale in the way you describe. I have not encountered a situation where they did not match. Did you perhaps change the Primary Axis settings? That is the only thing I can imagine that might switch the colors (though it shouldn't).

If you place a marker, the marker readings will also indicate which curve goes with which axis. Or you can use the Data menu to display the graph data, which will show all the values for magnitude and phase, which will tell you which line is which. Finally, the Smith chart graph will be in the same color as the magnitude graph.

I suspect that the blue curve is in fact magnitude, which means your readings are very far from what they should be. That's why I suspected an error in the OSL calibration procedure or in the hookup of the DC.

You can't recreate the OSL info from what you saved. You will have to re-do the OSL calibration. There is a Save Debug Info item in the File menu that allows you to save and then reload enough info to recreate the state of the software, but it is intended for basic debugging, hasn't proven all that useful and has not been updated to include OSL info. If you want to save OSL info you can select OSL Info in the Data menu, and then save the displayed data, but there is no way to reload it.

> > >
> > > By not having done phase cal, do you mean you haven't calibrated the PDM inversion? That could definitely distort the measurement. I also note that your wait time is 0, which rarely gives good results in Reflection mode. Any glitch that occurs during the O, S or L calibrations will show up in every subsequent measurement, along with any glitch that arises in the measurement itself. Use Auto Wait or at least 20 ms wait time even for the wide video filter.

From: Mark Burgin
Topic: 8171 Message: 8189

HI Jim
I'm pretty certain that your problem is caused by too much gain in the PLO loop. As I said, for me it was caused by the bug in handling the 4112 but it seems that you have eliminated that as a possibility. When it happened to me, it was very similar to your problem. It was noisy up to about 190MHz and fine at higher frequencies. Look for messages on the groups dated around 2nd Dec. 2010 with title "Software changes needed to support the ADF4112/ADF4113 in PLO1 and PLO2" to see the discussions.
I suppose there are several other things that could cause the gain to be too high. Have you double checked the values of R23 (the curent setting resistor), R1, R2 and C1. Any of these being wrong could cause the issue. Are you using the recommended ROS-2150VW VCO?
Good luck
Mark

On Sat, Jun 18, 2011 at 1:16 PM, Sam <swetterlin@...<mailto:swetterlin@comcast.net>> wrote:

The dates of the two changes aren't exactly the same, but they were both incorporated into version 116 Rev. A before it was released.

In the next version, the PLL listings will be clearer. There will be an entry for "2326,4118" and another for "4112,4113". (Internally, the software still codes these as simply 2326 and 4112.)

For the present, you should be sure you have selected "4112".

Sam W.

Jim,
Have you verified that a PLL is indeed producing erratic output when it should be at a fixed frequency, or is the symptom simply disappearance of graph data below 140 MHz?
Sam W.

As I said, for me it was caused by the bug in handling the 4112 but it seems that you have eliminated that as a possibility. When it happened to me, it was very similar to your problem. It was noisy up to about 190MHz and fine at higher frequencies. Look for messages on the groups dated around 2nd Dec. 2010 with title "Software changes needed to support the ADF4112/ADF4113 in PLO1 and PLO2" to see the discussions.
> I suppose there are several other things that could cause the gain to be too high. Have you double checked the values of R23 (the curent setting resistor), R1, R2 and C1. Any of these being wrong could cause the issue. Are you using the recommended ROS-2150VW VCO?

Also, I understood that your MSA was working with the parallel port and with USB through the control board, so this problem manifested itself only with direct USB control of the modules. True?

True. BUT:
1. I always had some dirty floor in the low frequencies. Up to the 200 MHz area. After that there was a clear improvement in the response (similar to what Scotty mentions about the mismatch of the cavity filter that is supposed to be resolved with a series cap+resistor in the mixer output).
2. This never was to the extent of loosing signals or even the zero response hump.
3. I see a lot of noise in the log detector output that is not present at the input. I am exploring this area as we speak.

Sam,
I missed your previous email. A fixed frequency (0 span) does not change anything, the magnitude does not change and it shows the same amount of noise (the noise can be cleaned with the video filter though).

Well,
It might have been the log detector. The poor thing seems to have just died.
I hope it was painful.

From: Sam
Topic: 8171 Message: 8195

The log detector does not seem a likely culprit because its response is unaffected by the frequency the MSA is tuned to. Your loss of signal at low frequency also seems different from the "dirty floor", since the latter is actually an "excess signal" (probably cavity filter leakage). If possible, check the PLO1 output with a fixed frequency scan, or a slowly moving scan. Also check that PLO2 is fixed at 1024 MHz.
Sam W.

8196. Re: [spectrumanalyzer] Re: MSA oscillation

Yahoo group: spectrumanalyzer (2011)
Date: 2011-06-19 14:13:03 UTC
From: Jim Hontoria
Topic: 8171 Message: 8196

While rebuilding my log detector I notice that there is a 0.001 cap (C13) at its output.. In addition, the input pin of the ADC has C12 (C21 for the phase ADC) , of the same size. Both caps are in parallel with the video filters. Should their value be added to that of the filter caps in the Configuration Table?

Theoretically, yes, but it will make no difference if you do so. The only exception is that when there is no video filter cap, the software doesn't like to have a zero value, but it will fudge the value itself. The video filter cap values are used only for fairly crude calculations, such as how long to wait after inverting the PDM. Those calculations are done conservatively so small errors in cap values have no practical effect.

8198. Confusion concerning using DDS 3 as a tracking generator

Yahoo group: spectrumanalyzer (2011)

From: Mark Burgin
Topic: 8198 Message: 8198

Hi all
I have just started building up the modules for the TG and VNA. My basic SA is complete and works fine. The first TG module I have completed is DDS3. I tested it and it appeared to work well and so I though I would try using DDS3 as a tracking generator to characterise a filter.
However, whenever I click on "Command DDS 3" or "DDS 3 Track", the spectrum ananlyzer display changes to a noisy flat line along the bottom of the display. For example, I have the SA set to sweep from 0 to 1MHz so that I can see the zero response hump on the display. If I then open the special tests window and set DDS 3 to 5 MHz and click on "Command DDS 3", and then "Continue" the scan, I just get a noisy flat line at -100db or so. If I Check the DDS 3 output with a scope, it has correctly been set to 5MHz.
I have had a look at the digital command signals to DDS 1 and 3 on a scope and they all look very clean and so it doesn't look like a crosstalk problem with the control signals.
I can understand that if I use DDS 1 as a tracking generator, normal SA functionality would be upset, but I can't understand why SA functionality is broken by using DDS 3 as the generator. What am I doing wrong?
Thanks
Mark

Hi,

Funny, I noticed the same behaviour. I have used the dds3 for scanning my narrow filter but now it doesn't seem to work anymore. I'll try an older version of the software to see if that will work...

On the site there is a mention of: Primary Function: Enabled
but I can't seem to find that button

Simon

Hi Mark,
 You are doing nothing wrong. Version 115 Rev G works as it should. There seems to be a software bug starting with the first beta release of Version 116. I'll get Sam involved.
Scotty

That was an obscure one. The error occurred between 116-2a and 116-3a, whose changes all involved USB fixes. But in the course of those changes, a carriage return got deleted in [CreateCmdAllArray], which created this line:

end if 'USB:05/12/2010 thisstep = rememberthisstep

The second half of that line is supposed to be a free-standing command, but instead it got incorporated into the comment of the "end if" line. The next release will fix this, but if you want to fix your code, search for the above line and replace it with:

end if 'USB:05/12/2010
thisstep = rememberthisstep

complete and works fine.Â The first TG module I have completed is DDS3.Â I tested it and it appeared to work well and so I though I would try using DDS3 as a tracking generator to characterise a filter.However, whenever I click on "Command DDS 3" or "DDS 3 Track", the spectrum ananlyzer display changes to a noisy flat line along the bottom of the display.Â For example, I have the SA set to sweep from 0 to 1MHz so that I can see the zero response hump on the display.Â If I then open the special tests window and set DDS 3 to 5 MHz and click on "Command DDS 3", and then "Continue" the scan, I just get a noisy flat line at -100db or so. Â If I Check the DDS 3 output with a scope, it has correctly been set to 5MHz.I have had a look at the digital command signals to DDS 1 and 3 on a scope and they all look very clean and so it doesn't look like a crosstalk problem
> with the control signals.I can understand that if I use DDS 1 as a tracking generator, normal SA functionality would be upset, but I can't understand why SA functionality is broken by using DDS 3 as the generator.Â What am I doing wrong?ThanksMark

Subject: [spectrumanalyzer] Re: Confusion concerning using DDS 3 as a tracking generator

That was an obscure one. The error occurred between 116-2a and 116-3a, whose changes all involved USB fixes. But in the course of those changes, a carriage return got deleted in [CreateCmdAllArray], which created this line:

end if 'USB:05/12/2010 thisstep = rememberthisstep

The second half of that line is supposed to be a free-standing command, but instead it got incorporated into the comment of the "end if" line. The next release will fix this, but if you want to fix your code, search for the above line and replace it with:

end if 'USB:05/12/2010
thisstep = rememberthisstep

8205. 3G Band Phase Polarity

Yahoo group: spectrumanalyzer (2011)
Date: 2011-06-20 04:14:25 UTC
From: forbes3100
Topic: 8205 Message: 8205

While we're fixing code I may have a couple more for you:

1) Check the phase polarity in 3G mode-- is it my hardware? Or is it inverted?

2) A *very* minor fix: the CrystalParameters routine will fail its test (if un-commented-out) due to Fdb3A and Fdb3B not being on either side of Fs. The BW is right so the rest of the test passes. I see these were derived from Jack Smith's methodology 3 test. Fdb3A=20.014599, Fdb3B=20.016655 will work fine.

Topic: 8205 Message: 8207

You are correct on 3G phase polarity if using released version 115. This is fixed in all the version 116 betas.

I don't follow the Crystal Parameters bug. Are you saying it claims it can't find the 3 dB points even when they are actually there?

Hi,

I had a similair problem but on a other frequency. The TG signal would dip at around 350mhz (zcomm vco's and home made pcb). I added two more by-pass caps, 0.1uF, on the powersupply trace just after the fb to the vco's and the problem went away. Nice straight line now....

Subject: [spectrumanalyzer] Re: MSA oscillation

The log detector does not seem a likely culprit because its response is unaffected by the frequency the MSA is tuned to. Your loss of signal at low frequency also seems different from the "dirty floor", since the latter is actually an "excess signal" (probably cavity filter leakage). If possible, check the PLO1 output with a fixed frequency scan, or a slowly moving scan. Also check that PLO2 is fixed at 1024 MHz.

Good to know it's fixed in 116, thanks.

The CrystalParameters routine itself is good. It's only the test values that are slightly wrong in a way that doesn't matter to the results since the BW is correct, but CrystalParameters is checking for Fdb3A < Fs which isn't true here. I guess the checks were added after the test was commented out.

OK, now I get it. That test code near the beginning of the program was created long ago and then commented out, and the parameters for the function it calls were subsequently changed. I have now deleted the commented-out test code.

8212. Raised noise floor when using DDS 3 at 10.7MHz as a signal source for SA - Poor RF-IF isolation in Mixer 1?

Yahoo group: spectrumanalyzer (2011)
Date: 2011-06-20 23:01:17 UTC
From: Mark Burgin
Topic: 8212 Message: 8212

Hi Everyone
As I mentioned in a previous posting, I have just built DDS 3 and am trying to use it to measure the performance of one of my resolution filters. Once the software bug was fixed (thanks Sam) everything more or less worked as expected but I noticed one peculiarity which I am unable to fully explain.
If I connect DDS 3 output to the SA input, set DDS 3 to output 10.7MHz, and do a sweep of the SA (any frequency range), I see that the noise floor across the whole band has raised to approx -60dBm. If I disconnect the DD3 output from the SA input, the noise floor returns to less than -100dBm. Or if I tune DDS 3 to a different frequency, 10MHz for example, the noise floor lowers back to its normal place. It seems that the output from DDS 3 is leaking through to the log detector somehow when it is set to the IF frequency. Note that I have not built or connected Mixer 3, Mixer 4, PLO 3 or the Phase Detector - it is just the basic SA + DDS 3 used as the signal source.
I think I understand why this is happening. The DDS output is rich in harmonics and one of them will be at 16 * 64MHz - 10.7Mhz = 1013.3MHz - the 1st IF frequency! If this leaks through Mixer 1, it will eventually appear as a 10.7Mhz signal at the Log Detector. I have confirmed this to some degree since, if I insert a 10.7MHz bandpass filter between DDS 3 output and the SA input eliminating the harmonics, the problem goes away.
But what I don't understand is why the effect is so large. Looking at the data sheet for the ADE-11X, the RF-IF isolation at 1GHz is about 20db. By tuning DDS 3 slightly off 10.7MHz to avoid the noise floor issue, I have measured the amplitude of the (15*64MHz - 10.7MHz) and (14*64MHz - 10.7MHz) harmonics and both are around -55dBm and so, if the 16th harmonic is similar, I would expect that the interference level should be less than -75dBm, but I am see about -60dBm.
Have I just got a bad mixer with poor RF-IF isolation (only about 5dB!) or is there another explanation?
Thanks
Mark

Hi Mark,
 You have your formula almost correct:
16 * 64MHz - 10.7Mhz = 1013.3MHz - the 1st IF frequency
it is really
16 * 64MHz - 10.7Mhz = 1013.3MHz, where 10.7 is the commanded DDS3
This is an alias and very powerful at 1013.3 MHz. This is the configuration when sweeping the cavity filter when the MSA is fully constructed.
  More specifically the formula for the output of the DDS is:
N * 64MHz +/- C, where N is any whole number, and C is the commanded DDS output.
I think your levels are about right.
 Scotty

Another good reason to use a low pass filter.
Interestingly, issues with high frequency (>1 GHz) components of the TG (whether the true TG or DDS3) seem to arise mostly when working with frequencies in the 0-15 MHz range. This makes it quite easy to create a low pass filter that will zap the high frequencies and have minimal impact on the frequencies of interest. In fact, you could do it with a couple of ferrite beads, if you pick ones with the proper frequency range.

The phase sitll has glitch, see the photo here:
http://groups.yahoo.com/group/spectrumanalyzer/photos/album/608125393/pic/1301870247/view?picmode=&mode=tn&order=ordinal&start=61&count=20&dir=asc

To simplify the problem, I went back to VNA TX mode and meausre a cable. Before VAN TX mode calibriation, the phase looks ok, but once I calibrate a 'through' I got phase glitch.
I did do a initial phase cal. The cal data is different from your example.

```
---------------------
*Filter Path 1: CenterFreq=10.111660 MHz; Bandwidth=1.000000 kHz
*Calibrated 06/21/11 at 2.000000 MHz.
CalVersion= 1.03
MagTable=
* ADC dBm Phase in increasing order of ADC
0 -120.000 2.19
4965 -110.000 2.19
4989 -107.500 2.19
5041 -105.000 2.19
5116 -102.500 2.19
5249 -100.000 2.19
5457 -97.500 2.19
5817 -95.000 2.19
6263 -92.500 2.19
6816 -90.000 2.19
7233 -88.401 2.19
8063 -85.000 2.50
9369 -80.000 3.04
12015 -70.000 3.03
14676 -60.000 3.07
17392 -50.000 2.93
20092 -40.000 2.74
22828 -30.000 1.71
25658 -20.000 0.00
28446 -10.000 -0.15
29106 -7.500 -0.15
29755 -5.000 -0.15
30336 -2.500 -0.15
30720 0.000 -0.15
```

Thanks
Lin

>
> If you place a marker, the marker readings will also indicate which curve goes with which axis. Or you can use the Data menu to display the graph data, which will show all the values for magnitude and phase, which will tell you which line is which. Finally, the Smith chart graph will be in the same color as the magnitude graph.
>
> I suspect that the blue curve is in fact magnitude, which means your readings are very far from what they should be. That's why I suspected an error in the OSL calibration procedure or in the hookup of the DC.
>
> You can't recreate the OSL info from what you saved. You will have to re-do the OSL calibration. There is a Save Debug Info item in the File menu that allows you to save and then reload enough info to recreate the state of the software, but it is intended for basic debugging, hasn't proven all that useful and has not been updated to include OSL info. If you want to save OSL info you can select OSL Info in the Data menu, and then save the displayed data, but there is no way to reload it.

I also note that your wait time is 0, which rarely gives good results in Reflection mode. Any glitch that occurs during the O, S or L calibrations will show up in every subsequent measurement, along with any glitch that arises in the measurement itself. Use Auto Wait or at least 20 ms wait time even for the wide video filter.
> > > >
> > > > The color of very thin lines on a sharply contrasting background is not accurate on some monitors, and also gets distorted in jpegs. For compression, it is better to use .png files, which are accurate and are also very compact when the picture contains broad areas of flat color. (.tif files are good too, but I don't think Yahoo lets you upload them.) When I do use jpegs, I have gotten best results by using a dark brown rather than black background (to reduce the contrast), and using double-width graph lines.

Lin,
From your description, I gathered that you cabled the TG to the MSA input, did a Through calibration, and then did a scan with the same cable in place. But the overall slant in the phase graph indicates that there was a length change between the calibration and the scan.

I'm almost positive that the glitches are caused by an incorrect value for the PDM inversion. Did you follow the calibration procedure for determining that value? With an incorrect value, whenever the PDM is inverted, the phase value will be off by a fixed amount, which causes the phase graph to shift between two parallel paths. The shifts will occur both during calibration and during the cable scan, so you get more glitches than you might expect.

Sam W.

Sam
I just followed the steps your wrote in the inital calibration. Do you have another instruction to calibrate the phase detector?
Thanks
Lin

>
> I'm almost positive that the glitches are caused by an incorrect value for the PDM inversion. Did you follow the calibration procedure for determining that value? With an incorrect value, whenever the PDM is inverted, the phase value will be off by a fixed amount, which causes the phase graph to shift between two parallel paths. The shifts will occur both during calibration and during the cable scan, so you get more glitches than you might expect.

Sam
I just found some information on Soctty's website, looks like I did not do a PDM calibration. I will try it.

I suppose I should clarify in my "Initial Calibration" document that you must first calibrate the PDM inversion. This is a fairly automated procedure invoked through menu Setup->PDM Calibration, which opens a window that completely explains the procedure.

Sam
If you can put a reminder in your doc, it could be better.
After I did the PDM calibration, it is ok now, I put three photos here:
http://groups.yahoo.com/group/spectrumanalyzer/photos/album/608125393/pic/957908904/view?picmode=&mode=tn&order=ordinal&start=61&count=20&dir=asc

This is a 83 ohm resistor load, in reflection mode, I measured 12.2dB, the calculated value is 12.11dB.

The glithes are gone on the HPF and cable phase.

For the color problem, I found you setting is correct, but it does not disply correct, unless I doulbe click the scale open and close the pop windows.

Thanks
Lin

8222. Re: [spectrumanalyzer] Re: MSA oscillation

Yahoo group: spectrumanalyzer (2011)
Date: 2011-06-24 12:03:16 UTC
From: Jim Hontoria
Topic: 8171 Message: 8222

Hi Mark,

Thanks for the feedback. I had an issue with the log detector failing and took a few days to get a replacement.
The MSA is back in operation with the same noise/ oscillation problem. The point is that the PLO1 was working fine some time ago, albeit with the low frequency oscillation. However, that oscillation never masked the zero response hump.Simply, it doesn't show up at all. I haven't touched the PLO and Iam getting decent control signals. At the zero hump setting, all I get is a uniform, 40 dB amplitude, noise band.
A 0 to 1000 scan shows that band extending up to 240 MHz where it drops to a lower level noise band about 10dB in amplitude all the way to 1000 MHz.
The video filters do not have any effect whatsoever (but I have verify their operation).
The second noise band is caused somewhere after the IF ampilifier, whereas the under 240MHz band originates before it, mostl ikely at the PLO.
Jim W1JGH

From: william sprowls
Topic: 8171 Message: 8223

Hi Jim,
 You first posted your problem a long time ago and it initiated a trouble shooting procedure. This resulted in changing the ADF4112 current from 5 ma to 1.25 ma. Because you had not posted the problem after the software change (until recently), I "assumed" that cured your problem. Don't you just love that word?
 I suggest this: All of your software should be in a single folder, probably called "MSA_Software". Zip the entire folder and attach it to an email to me. (wsprowls@...). I will look to see if anything is obvious.

Hi Mark, Thanks for the feedback. I had an issue with the log detector failing and took a few days to get a replacement. The MSA is back in operation with the same noise/ oscillation problem. The point is that the PLO1 was working fine some time ago, albeit with the low frequency oscillation. However, that oscillation never masked the zero response hump.Simply, it doesn't show up at all. I haven't touched the PLO and Iam getting decent control signals. At the zero hump setting, all I get is a uniform, 40 dB amplitude, noise band.
A 0 to 1000 scan shows that band extending up to 240 MHz where it drops to a lower level noise band about 10dB in amplitude all the way to 1000 MHz. The video filters do not have any effect whatsoever (but I have verify their operation).
The second noise band is caused somewhere after the IF ampilifier, whereas the under 240MHz band originates before it, mostl ikely at the PLO.Jim W1JGH

HI JimI'm pretty certain that your problem is caused by too much gain in the PLO loop. As I said, for me it was caused by the bug in handling the 4112 but it seems that you have eliminated that as a possibility. When it happened to me, it was very similar to your problem. It was noisy up to about 190MHz and fine at higher frequencies. Look for messages on the groups dated around 2nd Dec. 2010 with title "Software changes needed to support the ADF4112/ADF4113 in PLO1 and PLO2" to see the discussions.
I suppose there are several other things that could cause the gain to be too high. Have you double checked the values of R23 (the curent setting resistor), R1, R2 and C1. Any of these being wrong could cause the issue. Are you using the recommended ROS-2150VW VCO?
Good luckMark

Ok. So it is not the USB software, unless that section of the code anyway.
The 0 -140 MHz noise/oscillation problem still remains. Any takers on this one? Jim W1JGH
On Sat, Jun 18, 2011 at 1:16 PM, Sam <swetterlin@...> wrote:
The dates of the two changes aren't exactly the same, but they were both incorporated into version 116 Rev. A before it was released.

In the next version, the PLL listings will be clearer. There will be an entry for "2326,4118" and another for "4112,4113". (Internally, the software still codes these as simply 2326 and 4112.)

For the present, you should be sure you have selected "4112".

8224. Re: VNA reflection mode questions for V116_4i_beta

Yahoo group: spectrumanalyzer (2011)
Date: 2011-06-24 13:45:53 UTC
From: Sam
Topic: 8178 Message: 8224

Regarding the color. Do you mean that when you start up the colors are reversed, but when you open and then close the Y-axis preferences window, the colors are correct? That would be very odd.

Your graph looks good, but I noticed that the phase graph starts negative and steadily gets more negative. This means that on the Smith chart the graph would be a small arc rather than a single point. I'll take a shot in the dark and guess that you calibrated with commercial standards that have the open and short implemented at the front of the connector (i.e. the calibration plane is at the front), whereas you have the 83 ohm resistor mounted on the back of a connector. That means your true DUT is the resistor at the end of a short transmission line. That transmission line (the connector) creates the non-zero phase. If my guess is correct, you can eliminate the delay by adjusting Plane Extension to move the reference plane from the front to the back of the connector.

> > > > > >
> > > > > > I'm almost positive that the glitches are caused by an incorrect value for the PDM inversion. Did you follow the calibration procedure for determining that value? With an incorrect value, whenever the PDM is inverted, the phase value will be off by a fixed amount, which causes the phase graph to shift between two parallel paths. The shifts will occur both during calibration and during the cable scan, so you get more glitches than you might expect.

8225. Re: [spectrumanalyzer] Re: MSA oscillation

Yahoo group: spectrumanalyzer (2011)
Date: 2011-06-24 14:00:12 UTC
From: Jim Hontoria
Topic: 8171 Message: 8225

Some progress: The oscillation band going all the way to 1000 MHz is caused by overloading of the dataclk. Disconecting DDS 3 and PLO3 eliminated that effect. I will deal with that later by installing a buffer.

I injected a 300 MHz signal and I got:
-An oscillation up to 240MHz about 15-20 dB in amplitude.
-At 240 MHz the oscillation disappears and the base line drops 30 dB and stays at that level all the way to 1000MHz with very little noise.
- Nice clean and strong signals at 300 and 600 and 900 harmonics.
Removed the 300 signal, and terminated the MSA input with 50 ohm. Checked the zero response: it continues being masked by the noise. No indication whatsoever.

From: Jim Hontoria
Topic: 8171 Message: 8226

I will also include the graph I am getiing with the drop at 128 MHz. You will note that the oscillation seems to increase up to that frequency and then it suddenly dies off..

8227. RE: [spectrumanalyzer] Re: MSA oscillation

Yahoo group: spectrumanalyzer (2011)
Date: 2011-06-24 14:46:32 UTC
From: Mark Burgin
Topic: 8171 Message: 8227

Hi Scotty

I believe it was me who had the problem that resulted in the software change from 5ma to 1.25ma and not Jim. The software change fixed my problem as, I believe, I reported at the time. Jim's problem is more recent, and, it seems, not related to the same software issue.

Mark

Hi Jim,
You first posted your problem a long time ago and it initiated a trouble shooting procedure. This resulted in changing the ADF4112 current from 5 ma to 1.25 ma. Because you had not posted the problem after the software change (until recently), I "assumed" that cured your problem. Don't you just love that word?
I suggest this: All of your software should be in a single folder, probably called "MSA_Software". Zip the entire folder and attach it to an email to me. (wsprowls@yahoo.com). I will look to see if anything is obvious.
Scotty

Hi Mark,

Thanks for the feedback. I had an issue with the log detector failing and took a few days to get a replacement.
The MSA is back in operation with the same noise/ oscillation problem. The point is that the PLO1 was working fine some time ago, albeit with the low frequency oscillation. However, that oscillation never masked the zero response hump.Simply, it doesn't show up at all. I haven't touched the PLO and Iam getting decent control signals. At the zero hump setting, all I get is a uniform, 40 dB amplitude, noise band.
A 0 to 1000 scan shows that band extending up to 240 MHz where it drops to a lower level noise band about 10dB in amplitude all the way to 1000 MHz. The video filters do not have any effect whatsoever (but I have verify their operation).
The second noise band is caused somewhere after the IF ampilifier, whereas the under 240MHz band originates before it, mostl ikely at the PLO.

<mark@mburgin.co.uk</mc/compose?to=mark@mburgin.co.uk>> wrote:

HI Jim

I'm pretty certain that your problem is caused by too much gain in the PLO loop. As I said, for me it was caused by the bug in handling the 4112 but it seems that you have eliminated that as a possibility. When it happened to me, it was very similar to your problem. It was noisy up to about 190MHz and fine at higher frequencies. Look for messages on the groups dated around 2nd Dec. 2010 with title "Software changes needed to support the ADF4112/ADF4113 in PLO1 and PLO2" to see the discussions.

I suppose there are several other things that could cause the gain to be too high. Have you double checked the values of R23 (the curent setting resistor), R1, R2 and C1. Any of these being wrong could cause the issue. Are you using the recommended ROS-2150VW VCO?

Good luck

Mark

Ok. So it is not the USB software, unless that section of the code anyway.

The 0 -140 MHz noise/oscillation problem still remains. Any takers on this one?

<swetterlin@comcast.net</mc/compose?to=swetterlin@comcast.net>> wrote:

The dates of the two changes aren't exactly the same, but they were both incorporated into version 116 Rev. A before it was released.

In the next version, the PLL listings will be clearer. There will be an entry for "2326,4118" and another for "4112,4113". (Internally, the software still codes these as simply 2326 and 4112.)

For the present, you should be sure you have selected "4112".

Sam
"Do you mean that when you start up the colors are reversed, but when you open and then close the Y-axis preferences window, the colors are correct?"
Yes, I have to do so to make the color correct.

For the phase drop, that may caused by my Open calibration, where I did not extend the center pin to the plane. I can creat a OPEN cal kit to redo that.
Thanks
Lin

>
> Your graph looks good, but I noticed that the phase graph starts negative and steadily gets more negative. This means that on the Smith chart the graph would be a small arc rather than a single point. I'll take a shot in the dark and guess that you calibrated with commercial standards that have the open and short implemented at the front of the connector (i.e. the calibration plane is at the front), whereas you have the 83 ohm resistor mounted on the back of a connector. That means your true DUT is the resistor at the end of a short transmission line. That transmission line (the connector) creates the non-zero phase. If my guess is correct, you can eliminate the delay by adjusting Plane Extension to move the reference plane from the front to the back of the connector.

> > > > > > >
> > > > > > > I'm almost positive that the glitches are caused by an incorrect value for the PDM inversion. Did you follow the calibration procedure for determining that value? With an incorrect value, whenever the PDM is inverted, the phase value will be off by a fixed amount, which causes the phase graph to shift between two parallel paths. The shifts will occur both during calibration and during the cable scan, so you get more glitches than you might expect.

Before VAN TX mode calibriation, the phase looks ok, but once I calibrate a 'through' I got
phase glitch.

Sam
During the PDM calibration, the font in that menu looks like too big on my computer, and I could not see all the letters in the small frame.
Lin

This means that on the Smith chart the graph would be a small arc rather than a single point. I'll take a shot in the dark and guess that you calibrated with commercial standards that have the open and short implemented at the front of the connector (i.e. the calibration plane is at the front), whereas you have the 83 ohm resistor mounted on the back of a connector. That means your true DUT is the resistor at the end of a short transmission line. That transmission line (the connector) creates the non-zero phase. If my guess is correct, you can eliminate the delay by adjusting Plane Extension to move the reference plane from the front to the back of the connector.

> > > > > > > >
> > > > > > > > I'm almost positive that the glitches are caused by an incorrect value for

the PDM inversion. Did you follow the calibration procedure for determining that value? With an incorrect value, whenever the PDM is inverted, the phase value will be off by a fixed amount, which causes the phase graph to shift between two parallel paths. The shifts will occur both during calibration and during the cable scan, so you get more glitches than you might expect.

8230. Latest Beta software

Yahoo group: spectrumanalyzer (2011)
Date: 2011-06-24 18:43:12 UTC
From: Sam
Topic: 8230 Message: 8230

I have posted in the Files section the latest beta version of the software (MSA_version116-4k...) This mostly has minor fixes from the previous version, some of which were mentioned in prior postings. Unless some bugs are found in the next week or so, this will likely become the next official release.

One interested feature that Scotty came up with is the ability to do phase noise plots. This only works for fairly noisy signals, since otherwise you will mostly be viewing the MSA's own phase noise. It can plot the noise on either side of a signal's center frequency, using the log scale normally used for such plots. The x-axis will display the offset from the center frequency, rather than the actual signal frequency. To use it you set the Base Frequency (Sweep Parameters window) to the signal center frequency, select a frequency range such as 1 kHz to 1 MHz, or -1 MHz to -1 kHz, (those values are offsets from the center frequency and select log sweep. Note that it was not possible before to do log sweeps with negative frequency values.

Sam W.

Which text is too big? Does it run off the right edge of the window, or is it truncated somewhat inside the edge?
Sam W.

Topic: 8178 Message: 8232

Here is what I think happened with the color: For the Dark Appearance, normally phase is yellow and magnitude is blue. At some point you decided to reverse those colors, so you used the Y-axis windows to select the new colors for the traces. Then you saved those settings with Save Prefs. When the preference file is loaded at startup, your custom trace colors are used for the traces themselves, but the Dark Appearance settings are used for the color of the axis labels. I will see about fixing that, but here is a better way to make a permanent change to the color scheme:

1.Use menu Options->Appearances to open the Graph Appearance window.
2. Change the trace colors by clicking on the Y1 or Y2 box and then selecting the desired color.
3. When you have the colors you want, click Save as Preset. This lets you save the color scheme under a name that you chose. Enter the name and click Save. Your colors will now be implemented.
4. Use File->Save Prefs to update the preferences file to include the new color scheme in the list of Appearances, so it will still be available next time you start up.

From then on, when you start up, the colors will match the newly defined Appearance. If you want to temporarily select another appearance (such as Light for printing), you can do so in the Sweep Parameters window and later switch back to your custom Appearance by just selecting its name in the Appearances list.

On the other hand, if your reversal of the Dark colors was not intentional and you are OK with the default colors, you can restore them to their default values by selecting the Light Appearance and immediately selecting the Dark Appearance, which will override your custom trace color selection. You can then Save Prefs to make the change permanent.

Sam
I will try what you said for the color.
For the 83 ohm phase tilt, I corrected today, the figures are here:
http://groups.yahoo.com/group/spectrumanalyzer/photos/album/608125393/pic/949537787/view?picmode=&mode=tn&order=ordinal&start=61&count=20&dir=asc

As what you said, there is a very short lengh (might be 2mm) between the cal kit plan and the test fixture plane. After I created a set of cal kits, and use the same F connector for fxiture as cal kits used, the phase not is flat.
The resistor value is not 83 ohm, it is a 82.5 ohm 1%. the calculated return loss should be: 12.21dB typical, 12.04dB min, 12.37dB max
What I meausred is 12.244dB, which is very close to the typical value 12.21dB.
Thanks
Lin

> Here is what I think happened with the color: For the Dark Appearance, normally phase is yellow and magnitude is blue. At some point you decided to reverse those colors, so you used the Y-axis windows to select the new colors for the traces. Then you saved those settings with Save Prefs. When the preference file is loaded at startup, your custom trace colors are used for the traces themselves, but the Dark Appearance settings are used for the color of the axis labels. I will see about fixing that, but here is a better way to make a permanent change to the color scheme:
>
> 1.Use menu Options->Appearances to open the Graph Appearance window.
> 2. Change the trace colors by clicking on the Y1 or Y2 box and then selecting the desired color.
> 3. When you have the colors you want, click Save as Preset. This lets you save the color scheme under a name that you chose. Enter the name and click Save. Your colors will now be implemented.
> 4. Use File->Save Prefs to update the preferences file to include the new color scheme in the list of Appearances, so it will still be available next time you start up.
>
> From then on, when you start up, the colors will match the newly defined Appearance. If you want to temporarily select another appearance (such as Light for printing), you can do so in the Sweep Parameters window and later switch back to your custom Appearance by just selecting its name in the Appearances list.
>
> On the other hand, if your reversal of the Dark colors was not intentional and you are OK with the default colors, you can restore them to their default values by selecting the Light Appearance and immediately selecting the Dark Appearance, which will override your custom trace color selection. You can then Save Prefs to make the change permanent.

This means that on the Smith chart the graph would be a small arc rather than a single point. I'll take a shot in the dark and guess that you calibrated with commercial standards that have the open and short implemented at the front of the connector (i.e. the calibration plane is at the front), whereas you have the 83 ohm resistor mounted on the back of a connector. That means your true DUT is the resistor at the end of a short transmission line. That transmission line (the connector) creates the non-zero phase. If my guess is correct, you can eliminate the delay by adjusting Plane Extension to move the reference plane from the front to the back of the connector.

Those results are excellent. Magnitude is right on, and phase is reasonably close to zero. At 1 GHz, 1 mm in a connector is about 1.75 degrees of phase delay, and for the round-trip represented by reflection it is double that. So it is hard to get picky about phase measurements at such frequencies unless you are confident all connectors--the ones used for calibration and the ones used for DUTs--are all exactly the same length with exactly the same electrical characteristics. I don't think quality is on the top of the manufacturer's mind for F connectors. But yours are giving good results.

Another point on color: each axis has a main color and two secondary colors. The secondary colors are used for reference lines, and in the Two-Port module for additional graphs on that axis. If you reverse the colors for the axes, you may want to reverse all of them. The idea was to use blues/greens for one axis and yellow/reds for the other, which makes it clearer which traces go with which axis. But, the bottom line is that the Appearances options are there so you can do it any way you want.

Sam
3G band PDM phase compensation might also need to inverse after we inverse the phase, otherwise, we will see this:
http://groups.yahoo.com/group/spectrumanalyzer/photos/album/608125393/pic/2029992484/view?picmode=&mode=tn&order=ordinal&start=61&count=20&dir=asc

Thanks
Lin

Lin,
Everything in 3G is like looking in a mirror so it's easy to get something backwards. I'm not sure why this would not have shown up earlier though. What did you get for your PDM inversion? If it differs from 180 by about 18 degrees or so then I would guess you are correct.
Sam W.

Sam
The photo shows there are two steps during the phase inversion, the first is the original, and the second is the same as the first. I think the second is the PDM correction data, it just compensate in a wrong direction.
Lin

This means that on the Smith chart the graph would be a small arc rather than a single point. I'll take a shot in the dark and guess that you calibrated with commercial standards that have the open and short implemented at the front of the connector (i.e. the calibration plane is at the front), whereas you have the 83 ohm resistor mounted on the back of a connector. That means your true DUT is the resistor at the end of a short transmission line. That transmission line (the connector) creates the non-zero phase. If my guess is correct, you can eliminate the delay by adjusting Plane Extension to move the reference plane from the front to the back of the connector.

8238. Re: VNA reflection mode questions for V116_4i_beta

Yahoo group: spectrumanalyzer (2011)
Date: 2011-06-27 14:21:16 UTC
From: Sam
Topic: 8178 Message: 8238

Yes, the negation of phase in 3G should occur after the PDM inversion is applied, and after applying the phase correction from phase calibration. To fix that, locate this line:

if FreqMode=3 then phase=0-phase

and move it several lines down so it occurs immediately after this line:

phase=phase-difPhase

Hopefully, that will do the trick.

Sam W.

phase measurements at such frequencies unless you are confident all connectors--the ones used for calibration and the ones used for DUTs--are all exactly the same length with exactly the same electrical characteristics. I don't think quality is on the top of the manufacturer's mind for F connectors. But yours are giving good results.
> > > >
> > > > Another point on color: each axis has a main color and two secondary colors. The secondary colors are used for reference lines, and in the Two-Port module for additional graphs on that axis. If you reverse the colors for the axes, you may want to reverse all of them. The idea was to use blues/greens for one axis and yellow/reds for the other, which makes it clearer which traces go with which axis. But, the bottom line is that the Appearances options are there so you can do it any way you want.

8239. IFR A7550 Spectrum analyzer

Yahoo group: spectrumanalyzer (2011)
Date: 2011-06-27 21:04:56 UTC
From: Don
Topic: 8239 Message: 8239

Hi all,

Just joined this group. I have the option of buying an IFR A7550 SpecAn. The machine powers up just fine and displays the graticule and the center frequency, ref level, sweep rate and Res BW on the screen. Also shows a trace on the screen. There is an "UNCAL" message on the screen where it usually shows the graticule unit (dBm, dBV etc). Reading the manual, it appears that the "UNCAL" message appears if the sweep rate is not optimal for the selected sweep width and RBW. I think if I can reduce the sweep rate, that the "UNCAL" message will go away. The problem is that NONE of the keys on the keypad do anything when pressed. Any idea if this is a simple fix or if I should stay away from it? TIA for your opinions.

8240. Re: IFR A7550 Spectrum analyzer

Topic: 8239 Message: 8240

My apologies to the members of this Forum for posting inappropriately. I found this Forum while searching for info on the IFR A7550 spectrum analyzer and found a thread discussing said spectrum analyzer and therefore (erroneously) assumed that this was a general Spectrum analyzer Forum. A Forum member kindly contacted me offline and informed me that this Forum was specifically for a home brew Spectrum analyzer. Please disregard my original post (although if any of you have any opinions on it, I would like to hear them)

Don

8241. Re: VNA reflection mode questions for V116_4i_beta

Yahoo group: spectrumanalyzer (2011)
Date: 2011-06-28 03:28:21 UTC
From: inlinebeginner
Topic: 8178 Message: 8241

Sam
To fix the 3G band VNA mode phase:
original: phase = phase - (180+PDMinversionDeviation)
after fix:
if FreqMode=3 then phase = phase + (180+PDMinversionDeviation) else phase = phase - (180+PDMinversionDeviation)

I tried with above fix, 1G, 2G and 3G band phase are all correct. The code around that area with the fix should be:

```
....
if FreqMode=3 then phase=0-phase 'For 3G mode, true phase is negative of measured phase,
due to low side LO1 ver116-1b
'if PDM was inverted, subtract the inverted phase change
'The deviation in the PDM inversion from theoretical 180 deg is actually a fixed time
period
'invdeg is maintained as the actual inversion that occurs at 10.7 MHz. With a different
finalfreq,
'the deviation from 180 degrees will change.
if phaarray(thisstep,0)=1 then 'ver116-1b
PDMinversionDeviation=(invdeg-180)*finalfreq/10.7
if FreqMode=3 then phase = phase + (180+PDMinversionDeviation) else phase = phase -
(180+PDMinversionDeviation)
end if
phase=phase-difPhase 'SEW3: subtract correction for change of phase over signal level.

.....
```

Thanks
Lin

> > > > > > > > >
> > > > > > > > > Your graph looks good, but I noticed that the phase graph starts negative and steadily gets more negative. This means that on the Smith chart the graph would be a small arc rather than a single point. I'll take a shot in the dark and guess that you calibrated with commercial standards that have the open and short implemented at the front of the connector (i.e. the calibration plane is at the front), whereas you have the 83 ohm resistor mounted on the back of a connector. That means your true DUT is the resistor at the end of a short transmission line. That transmission line (the connector) creates the non-zero phase. If my guess is correct, you can eliminate the delay by adjusting Plane Extension to move the reference plane from the front to the back of the connector.

From: Sam
Topic: 8178 Message: 8243

It would be better just to move the line that negates phase, per my prior posting. That will also take care of the (small) adjustment that occurs due to phase calibration.
Sam W.

At 1 GHz, 1 mm in a connector is about 1.75 degrees of phase delay, and for the round-trip represented by reflection it is double that. So it is hard to get picky about phase measurements at such frequencies unless you are confident all connectors--the ones used for calibration and the ones used for DUTs--are all exactly the same length with exactly the same electrical characteristics. I don't think quality is on the top of the manufacturer's mind for F connectors. But yours are giving good results.
> > > > > >
> > > > > > Another point on color: each axis has a main color and two secondary colors. The secondary colors are used for reference lines, and in the Two-Port module for

additional graphs on that axis. If you reverse the colors for the axes, you may want to reverse all of them. The idea was to use blues/greens for one axis and yellow/reds for the other, which makes it clearer which traces go with which axis. But, the bottom line is that the Appearances options are there so you can do it any way you want.

So the window text is fine; the problem is with the button text. The buttons used the default text, which depends on your Windows theme settings. I have changed the code to use a specific, small font.
Sam W.

8245. Latest Bill of Materials

Yahoo group: spectrumanalyzer (2011)
Date: 2011-06-28 15:06:32 UTC
From: Eric Nystrom
Topic: 8245 Message: 8245

I am working on building the PLO modules and have a couple of questions.

I ordered from the BOM dated 2/13/2011

The BOM shows 10 75 ohm 1/4 w should be ordered, but the quantity in parenthesis is 16.

The total ordered should be changed to 20.

The BOM orders 10 68 pf capacitors, while the PLL schematic and parts list shows 680 pf
for C1 and C48.

Which is correct?

Eric Nystrom

You are correct on the qty 20 resistors. The capacitors should be 680 pF per the schematic, which is Digi-Key 311-1121-1-ND.

Thanks for the catch. I have uploaded the corrected BOM.
Sam W.

Sam,

I was reviewing the other schematics and it looks like the 68 pf are needed on
the
mixer 2, so they should stay on the BOM. It appears the 680 pf were an
omission.

Sam
I tried this line:
> > phase=phase-difPhase

For some reason, it does not work, that is why I added that fix. You may try on your MSA, in VNA transmission mode, with a cable between TG output and SA input.
Thanks
Lincheng Xiu

> > > > > > > > >
> > > > > > > > > Your graph looks good, but I noticed that the phase graph starts negative and steadily gets more negative. This means that on the Smith chart the graph would be a small arc rather than a single point. I'll take a shot in the dark and guess that you calibrated with commercial standards that have the open and short implemented at the front of the connector (i.e. the calibration plane is at the front), whereas you have the 83 ohm resistor mounted on the back of a connector. That means your true DUT is the resistor at the end of a short transmission line. That transmission line (the connector)

creates the non-zero phase. If my guess is correct, you can eliminate the delay by adjusting Plane Extension to move the reference plane from the front to the back of the connector.

8249. Re: VNA reflection mode questions for V116_4i_beta

Yahoo group: spectrumanalyzer (2011)
Date: 2011-06-28 16:31:23 UTC
From: Sam
Topic: 8178 Message: 8249

You don't add that line; rather, you move another line to place it after that line:

Locate this line:

if FreqMode=3 then phase=0-phase

and move it several lines down so it occurs immediately after this line:

phase=phase-difPhase

Sam W.

At 1 GHz, 1 mm in a connector is about 1.75 degrees of phase delay, and for the round-trip represented by reflection it is double that. So it is hard to get picky about phase measurements at such frequencies unless you are confident all connectors--the ones used for calibration and the ones used for DUTs--are all exactly the same length with exactly the same electrical characteristics. I don't think quality is on the top of the manufacturer's mind for F connectors. But yours are giving good results.

OK, I added the 68 pF back in. I also noticed that I had the correct Digi-Key number for the 680 pF, but not the right manufacturer's part number. It is now fixed.
Sam W.

8251. Re: VNA reflection mode questions for V116_4i_beta; now V116_4L_Beta

Yahoo group: spectrumanalyzer (2011)
Date: 2011-06-28 19:48:42 UTC
From: Sam
Topic: 8178 Message: 8251

I posted new beta software with this fix. In the course of testing this, I also discovered that the previous beta had an error that could disrupt the TG. I tested at 1G and 3G; my 1G/2G band switch is at the moment de-installed.

From: Eric Nystrom
Topic: 8245 Message: 8252

It appears that R3 (PLO board) a 470 ohm resistor is missing from the latest BOM also.

I assume the .0051 uf are to be used for C3 .005 uf on the PLO board.

One other thing relating to the BOM. 10uf 0805 X5R capacitors replaced the polarized
capacitors the boards were laid out for. It is a bit of a stretch fitting the 0805 on the pads.
Not sure of the original package, but it seems that a 1206 would be a better fit something
like a Digi Key 399-5091-1-ND

http://search.digikey.com/scripts/DkSearch/dksus.dll?Detail&name=399-5091-1-ND

Sam
116_4L_Beta fixed all the problems.
1) 3G phase fixed;
2) PDM menu botton font size fixed;
3) Axis Clolor matchs with its curve color, fixed
Thanks
Lin

reasonably close to zero. At 1 GHz, 1 mm in a connector is about 1.75 degrees of phase
delay, and for the round-trip represented by reflection it is double that. So it is hard to
get picky about phase measurements at such frequencies unless you are confident all
connectors--the ones used for calibration and the ones used for DUTs--are all exactly the
same length with exactly the same electrical characteristics. I don't think quality is on
the top of the manufacturer's mind for F connectors. But yours are giving good results.
> > > > > > > > > >
> > > > > > > > > > Another point on color: each axis has a main color and two secondary

colors. The secondary colors are used for reference lines, and in the Two-Port module for additional graphs on that axis. If you reverse the colors for the axes, you may want to reverse all of them. The idea was to use blues/greens for one axis and yellow/reds for the other, which makes it clearer which traces go with which axis. But, the bottom line is that the Appearances options are there so you can do it any way you want.

At some point you decided to reverse those colors, so you used the Y-axis windows to select the new colors for the traces. Then you saved those settings with Save Prefs. When the preference file is loaded at startup, your custom trace colors are used for the traces themselves, but the Dark Appearance settings are used for the color of the axis labels. I will see about fixing that, but here is a better way to make a permanent change to the color scheme:

Yes, I think the 470 ohm value was a change made after the original BOM (the one I started from when I did my update) was made. You are correct that the 0.005 uF capacitors on the schematic have an actual value of 0.0051 uF.

I picked the size 0805 10uF/16V caps to distinguish them from the size 1206 25V caps, but as you say, since the pads are 1206 that would be a better size to use. I imagine that the 25V caps are fatter than the 10V caps anyway.

I'll wait to see whether you discover any other discrepancies before posting a corrected BOM.

Sam,

The 25 volt caps on the power and control board were 0805 also. I double checked the BOM to make sure I did not make
a mistake in my order. It would be better if they were 1206 also.

I hope to have all the boards built within a couple of weeks so I will let you know if I find any
other missing parts. I am waiting until I am done to place my next order.

From: nealmartini
Topic: 8256 Message: 8256

Scotty,

I am trying to get a close in look at the performance of a signal source that runs at 620 MHz. I'd like to get a plot that goes from 1k to 1 M from the 620 MHz with a logrithmic x axis on the plot. I know how you got the phsae noise plot you posted for the SA's internal local oscillator, but was wondering how I might use the SA to generate a similar plot without replumbing the SA.

Any suggestions would be appreciated.

Neal

Neal
You need to use the latest beta software to get the log plot you are looking for:
1.Set the Base Frequency to 620 MHz.
2.Set the sweep range to start at 0.001 MHz and end at 1 MHz. Specify log sweep.
3. Use your narrowest RBW.

This will give you the desired sweep. The frequency axis will show the offsets from 620 MHz, rather than the net frequency. But keep in mind that your signal must have noise or spurs higher than the internal MSA phase noise in order for you to see anything useful.
Sam W.

Hi Sam,

Group delay seems to be broken in 116-4L (and i). I'm seeing a constant -2.78k instead of the result I see in 115-9e. It's only the "Grp Del(sec)" data that's wrong though-- "S21 Group Delay" is correct.

>
> One interested feature that Scotty came up with is the ability to do phase noise plots. This only works for fairly noisy signals, since otherwise you will mostly be viewing the MSA's own phase noise. It can plot the noise on either side of a signal's center frequency, using the log scale normally used for such plots. The x-axis will display the offset from the center frequency, rather than the actual signal frequency. To use it you set the Base Frequency (Sweep Parameters window) to the signal center frequency, select a frequency range such as 1 kHz to 1 MHz, or -1 MHz to -1 kHz, (those values are offsets from the center frequency and select log sweep. Note that it was not possible before to do log sweeps with negative frequency values.

Scott,
If you are willing to tinker with the code, find this line in uBestFitLine:

x=ReflectArray(i,0)

and change it to this:

x=ActualSignalFrequency(datatable(i,1))

That should fix it, though I have not tested it on real data.

This mostly has minor fixes from the previous version, some of which were mentioned in prior postings. Unless some bugs are found in the next week or so, this will likely become the next official release.
> > >
> > > One interested feature that Scotty came up with is the ability to do phase noise plots. This only works for fairly noisy signals, since otherwise you will mostly be viewing the MSA's own phase noise. It can plot the noise on either side of a signal's center frequency, using the log scale normally used for such plots. The x-axis will display the offset from the center frequency, rather than the actual signal frequency. To use it you set the Base Frequency (Sweep Parameters window) to the signal center frequency, select a frequency range such as 1 kHz to 1 MHz, or -1 MHz to -1 kHz, (those values are offsets from the center frequency and select log sweep. Note that it was not possible before to do log sweeps with negative frequency values.

Sam
You might want to fix the similar font size problem for:
1) Configureation manager
2) Sepcial test
http://groups.yahoo.com/group/spectrumanalyzer/photos/album/608125393/pic/115723472/view?picmode=&mode=tn&order=ordinal&start=61&count=20&dir=asc

some other menus may also need to change the same font size for better looking.
Thanks

Appearance, normally phase is yellow and magnitude is blue. At some point you decided to
reverse those colors, so you used the Y-axis windows to select the new colors for the
traces. Then you saved those settings with Save Prefs. When the preference file is loaded
at startup, your custom trace colors are used for the traces themselves, but the Dark
Appearance settings are used for the color of the axis labels. I will see about fixing

that, but here is a better way to make a permanent change to the color scheme:

> > > > > > > > > > > > > > Your graph looks good, but I noticed that the phase graph starts negative and steadily gets more negative. This means that on the Smith chart the graph would be a small arc rather than a single point. I'll take a shot in the dark and

guess that you calibrated with commercial standards that have the open and short implemented at the front of the connector (i.e. the calibration plane is at the front), whereas you have the 83 ohm resistor mounted on the back of a connector. That means your true DUT is the resistor at the end of a short transmission line. That transmission line (the connector) creates the non-zero phase. If my guess is correct, you can eliminate the delay by adjusting Plane Extension to move the reference plane from the front to the back of the connector.

Lin,
Your Windows settings must use an unusually large font. I can override that by specifying a particular font. I was originally under the impression that Liberty Basic used a specific default font, but it turns out LB lets Windows pick the default. So I should specify the default for each window, which I do for new windows and also for old windows when I run across the problem.

By the way, I saw your photos of your cal set. You described them as "F" connectors by which you meant female, but I took it to mean the F-style connectors used for cable TV connections. It appears to be a good quality set.
Sam W.

At some point you decided to reverse those colors, so you used the Y-axis windows to select the new colors for the traces. Then you saved those settings with Save Prefs. When the preference file is loaded at startup, your custom trace colors are used for the traces themselves, but the Dark Appearance settings are used for the color of the axis labels. I will see about fixing that, but here is a better way to make a permanent change to the color scheme:

> > > > > > > > > > > > > > > > > Your graph looks good, but I noticed that the phase graph starts negative and steadily gets more negative. This means that on the Smith chart the graph would be a small arc rather than a single point. I'll take a shot in the dark and guess that you calibrated with commercial standards that have the open and short implemented at the front of the connector (i.e. the calibration plane is at the front), whereas you have the 83 ohm resistor mounted on the back of a connector. That means your true DUT is the resistor at the end of a short transmission line. That transmission line (the connector) creates the non-zero phase. If my guess is correct, you can eliminate the delay by adjusting Plane Extension to move the reference plane from the front to the back of the connector.

Sam
I use a default setting on my windows. I can try to see if I can change that.
For "F connector" should be "SMA connector", female side, similar to thoese we used on SLIM modules, but the monting plane is a big square. I don't know how good the connector I used, looks high quality. I will upload a photo for that.
The can of the cal kits are from 75 ohm cable connector (male side). Just cut off the screw and use the rest of the metal as the round fence, and solder a end metal sheet.
Lin

At 1 GHz, 1 mm in a connector is about 1.75 degrees of phase delay, and for the round-trip represented by reflection it is double that. So it is hard to get picky about phase measurements at such frequencies unless you are confident all connectors--the ones used for calibration and the ones used for DUTs--are all exactly the same length with exactly the same electrical characteristics. I don't think quality is on the top of the manufacturer's mind for F connectors. But yours are giving good results.
> > > > > > > > > >
> > > > > > > > > > Another point on color: each axis has a main color and two secondary colors. The secondary colors are used for reference lines, and in the Two-Port module for additional graphs on that axis. If you reverse the colors for the axes, you may want to reverse all of them. The idea was to use blues/greens for one axis and yellow/reds for the other, which makes it clearer which traces go with which axis. But, the bottom line is that the Appearances options are there so you can do it any way you want.

Lin,
Actually, it is probably a good thing that you have a large font. It flushes out possible problems that would not otherwise be apparent.
Sam W.

At 1 GHz, 1 mm in a connector is about 1.75 degrees of phase delay, and for the round-trip represented by reflection it is double that. So it is hard to get picky about phase measurements at such frequencies unless you are confident all connectors--the ones used for calibration and the ones used for DUTs--are all exactly the same length with exactly the same electrical characteristics. I don't think quality is on the top of the manufacturer's mind for F connectors. But yours are giving good results.
> > > > > > > > > > >
> > > > > > > > > > > Another point on color: each axis has a main color and two

secondary colors. The secondary colors are used for reference lines, and in the Two-Port module for additional graphs on that axis. If you reverse the colors for the axes, you may want to reverse all of them. The idea was to use blues/greens for one axis and yellow/reds for the other, which makes it clearer which traces go with which axis. But, the bottom line is that the Appearances options are there so you can do it any way you want.

At some point you decided to reverse those colors, so you used the Y-axis windows to select the new colors for the traces. Then you saved those settings with Save Prefs. When the preference file is loaded at startup, your custom trace colors are used for the traces themselves, but the Dark Appearance settings are used for the color of the axis labels. I will see about fixing that, but here is a better way to make a permanent change to the color scheme:

> > > > > > > > > > > > > > > > > > > Your graph looks good, but I noticed that the phase graph starts negative and steadily gets more negative. This means that on the Smith chart the graph would be a small arc rather than a single point. I'll take a shot in the dark and guess that you calibrated with commercial standards that have the open and short implemented at the front of the connector (i.e. the calibration plane is at the front), whereas you have the 83 ohm resistor mounted on the back of a connector. That means your true DUT is the resistor at the end of a short transmission line. That transmission line (the connector) creates the non-zero phase. If my guess is correct, you can eliminate the delay by adjusting Plane Extension to move the reference plane from the front to the back of the connector.

Sam,
I believe that when the program starts and shows the zero response, the span is supposed to be 10 times the bandwidth of the RBW filter. The software is not doing that: it opens with the same bandwidth as the filter.
Also if you switch filters the zero response bandwidth remains constant.

From: Sam
Topic: 8178 Message: 8266

Jim,
The program starts up with whatever sweep range is in the preferences file, prefs.txt. The very first time it starts, there is no such file so it starts with a zero center and a span equal to 10 times the RBW. It then creates the preferences file with that data. If you re-save the prefs.txt file with different values, those become your startup values. The sweep range is never changed simply by changing RBW filters.

Also, I have noticed a tendency of people to post messages by replying to any-old-random message that has already been posted. That creates meaningless subject lines, very long threads and a whole lot of clutter attached to the end of the new message. It is much better to create a new thread.

Sam W.

8267. Web Page Editor

Hi All,
A quick question. I have been using Netscape Composer as my web page editor, using the wysiwyg style. I need a new editor for my XP computer and I am using Firefox as my browser. Can someone suggest a comparable editor (free, or course).
Scotty

I'm at even a more primitive level. I use MS Word and then save the document as html. That's why my web site is very bare bones--basically a list of downloadable documents.

Hi Sam;

Agreed, you can do a lot with a text editor, I use Note Tab Pro, it seems to work pretty well.

You might want to look at this page and then pick one that you like

http://www.godandscience.org/general/free_wsyiwyg_html_editors.html

SeaMonkey seems to be a re-run of Netscape page editor.

Scotty,

You might look at Wordpress, it was designed for blogs but does a good job with html too.

Another great thing about wordpress is that you can delegate pages to different authors. That way, Sam could write directly on many pages, and if you wanted me to make some construction instructions (like I did on my blog: http://alternet.us.com/?page_id=751) I could be given permissions for only that page.

Also, it's more work, and I don't know how to do it exactly, but Drupal is generic enough that I think it could completely replace the capabilities of the Yahoo Groups page if Yahoo decides to kill it. The only part I don't know about is the mailing list, but that's the most likely thing for Yahoo to keep.

I just took a quick look at the Wordpress site, and it appears to me that it is geared toward formatting things hosted on their web site. Is that correct?

There's 2 different ways to do wordpress.

there's wordpress.com and wordpress.org. the .com site hosts blogs for people. The .org site is geared toward the open source project concerned only with the software. On my blog, I pay for hosting at dreamhost and use wordpress to run the blog. I don't host anything on wordpress.com.

8275. T-Check

Yahoo group: spectrumanalyzer (2011)
Date: 2011-07-04 16:48:10 UTC
From: Sam
Topic: 8275 Message: 8275

Rohde & Schwarz has software to calculate a "T-Check" figure of merit for VNAs, based on reflection and transmission scans of a tee whose third branch is terminated in 50 ohms. A result of 100% is ideal and anything within 10% of that is considered very good; 15% deviation is acceptable. On commercial VNAs, this test would be performed after first doing full 10- or 12-term calibration. My objective is to achieve good results without the extra fuss, using normal OSL calibration for reflection and Through calibration for transmission, relying on attenuators to create a good source and load match. I put 7.7 dB on the TG output and 14 dB on the MSA input. I posted a photo of the results:

http://groups.yahoo.com/group/spectrumanalyzer/photos/album/252922278/pic/85655545/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc

Up to 200 MHz, the deviation was only about 1%; it gradually deteriorated but exceeded 10% (the green area in the photo) only just before reaching 1 GHz. I have reason to suspect the quality of the tee I used, which may have affected the high frequency performance.

The attenuators of course reduce the dynamic range unless you counter them with an amplifier, but the range is still good without an amp. I believe that up to a few hundred MHz, the attenuation could be cut in half and still achieve excellent results.

(Note the percentage deviations do not translate directly to percentage accuracy; they are simply the deviation from a perfect figure of merit.)

Sam W.

Topic: 8275 Message: 8277

It's now in the Files section under T-Check_HD_Install. To create the file to analyze, do reflection and transmission scans of the tee (after proper calibration), then open the Two-Port window and tell it to transfer Transmission to S21 and S12 and Reflection to S11 and S22. Note that due to the symmetry of the tee, you can re-use the forward scan data for the reverse data. Then save the file.

The T-Check software has a bug in that the Touchstone file data has to be in Hz. Therefore, you have to change the header line (beginning with "#") to Hz, and change the frequency data to Hz. I did the latter by opening the file in Notepad, copying all the data to Excel, using Text to Columns to get it entered properly, creating a new second column calculated to be 1000000 times the first column, copying everything except column 1 and pasting it back into Notepad and saving the file. In the process the first data line got messed up so I fixed it manually.

8278. Re: T-Check

Yahoo group: spectrumanalyzer (2011)
Date: 2011-07-05 14:04:13 UTC
From: Sam
Topic: 8275 Message: 8278

Well, the third arm fell off my tee while I was messing with it, so it was indeed defective. Here is a T-Check with another tee:

<http://groups.yahoo.com/group/spectrumanalyzer/photos/album/252922278/pic/942936460/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc>

This was actually a tiny bit worse at low frequency, but still very good, and it even improved at high frequency. Ranged from 0-5% deviation, with max of 10% being the goal.

If you do this test, it is best to put the target .s2p file freestanding on the C: drive; it is a bit awkward to navigate to a file in the T-Check software. (I think this software dates from pre-Windows 98.)

The actual meaning of the T-Check results is a bit obscure if you try to make it into something other than a pass/fail test. As I mentioned, it is not directly a measure of percentage accuracy. In terms of actual accuracy, S11 should ideally have been -9.54 dB and was very close to -9.65 dB all the way to 1 GHz. S21 should have been -3.52 dB and varied from -3.54 dB at 1 MHz to -3.46 dB at 1 GHz.

8280. Last BOM Update

Yahoo group: spectrumanalyzer (2011)
Date: 2011-07-05 17:57:20 UTC
From: Eric Nystrom
Topic: 8275 Message: 8280

Sam,

I am building the last two boards and found what I think are the last updates to the BOM.

The quantity for the 7SZ74 should be 3 instead of 2.
U5, U8, and U9 on the PDM

There should be 8 instead of 6 of the 330 nh inductors
2 on IF amplifier
2 on Mixer 4
2 on Mixer 2
2 1 on each DDS listed as .33 uh

And I am 1 short on the 10uf 16v X5R caps.

PLL 7x 3 = 21
DDS 2 x 2 = 4
IF AMP 2
PDM 2
MO 2
LOG DET 2
A to D 8

for a total of 41 instead of 40

Eric Nystrom

Thanks, I have now updated the posted BOM. I also posted a message about it yesterday, but my messages seem to be delivered by slow boat.

8282. PCMCIA Parallel port adapter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-07-14 00:43:52 UTC
From: Rex
Topic: 8282 Message: 8282

I am trying to use a pcmcia parallel port adapter for the spectrum analyzer. It shows up as LTP3 with a base range of FFF0 - FFF7.
What should I use as the address in the spectrum analyzer setup ?.
Thanks

rex

Hi Rex,
In the Hardware Configuration Manager Window, use FFF0. The MSA software adds 1 to that base number for Status port and 2 for Control Port.

Hi Scotty

I had originally tried using FFF0 and then HEX FFF0, but the specana software saves the latter as HEX 0. Neither works. The hardware works ok on another computer with an internal LPT port so I know its not a hardware issue. The device manager is showing the port is configured correctly and the device is functioning correctly.

Any other ideas or am I not entering the data correctly.

Thanks again

Rex

Rex,
Run the MSA program
Halt and under menu item Setup, open Hardware Configuration Manager
In LPT Port Address box,enter Hex FFF0(FFFzero, not o)
I tried it and it accepted it.

8286. GPIB/Serial Remote control on MSA for auto test?

Yahoo group: spectrumanalyzer (2011)
Date: 2011-07-15 19:38:38 UTC
From: inlinebeginner
Topic: 8286 Message: 8286

Sam
Do we have a plan to add GPIB/Serial remote control on MSA? If you need to search a spur over a wideband, or do 1000 times phase noise scan over a band for tuner, the remote control might be very useful. The simplest interface might be the serial port, RS232, for remote control. To use this remote function, we can use another serial port #2(can be created with a USB-Serial port converter) on the same PC and talk to the serial port of MSA. By writing some script (or program) connected with prot #2, we can get test data from MSA, if the script is also connected to other equipment, such as a sig gen or multimeter, via GPIB card, some complecated auto test system can be setup with MSA.
Thanks
Lin

Lin,
I have no plans to do so, though I have thought about the possibility of communication with another program. I think the best approach would be to put most of the action in a separate program, with communication occurring by that program creating a preferences file with required settings. The MSA would load those settings, do a scan, and if necessary save data to a file, which would be accessible to the second program. That second program would handle any GPIB communication.

8288. Bandwidth of crystal filters

Yahoo group: spectrumanalyzer (2011)
Date: 2011-07-16 03:23:02 UTC
From: Steve
Topic: 8288 Message: 8288

Scotty,

I'm trying to work through the design of crystal filters using the crystals you and Jerry distributed in 2009 and the information on your Crystal Ladder Filter Board <http://www.scottyspectrumanalyzer.com/pwb_clf_5.html> web page.

In a posting sometime ago, you suggested that it would be useful to have resolution bandwidth filters: 2 KHz; 5 to 10 KHz; 30 KHz ; and 100 KHz to 300 KHz.

What is the limit to the bandwidth of this type filter? Can these crystals and the technique described on your web page be used to construct the filters in the bandwidths you suggested?

Thanks.

Steve

Steve,
I believe Scotty once mentioned 7.5 kHz as the practical limit for that filter design. The Amplifilter has made it practical to get a very narrow filter--I got 250 Hz with those crystals--so I would suggest you go with the Amplifilter and also design something in the 2-7 kHz range. For the wider ones, the ceramic filters are very simple and perform well.

In the latest sissue of QEX there is an interesting article about the maximum bandwidth on can achieve with the ladde4r filter design!

Htis bandwidth depends on ths spacing of the series and parallel resonance of the individual x-tal.

Hi Jeff,
 If you don't use VNA, then leave PLO 1-J2 and PLO 3- J3 unconnected. They can be terminated in 50 ohms or left open.
Scotty

8298. Measuring Calibration Loads

Yahoo group: spectrumanalyzer (2011)
Date: 2011-07-27 21:32:25 UTC
From: Sam
Topic: 8298 Message: 8298

I have posted a file explaining methods to measure the DC resistance of OSL calibration Loads with great accuracy, even if you don't have a great DMM:

<http://www.wetterlin.org/sam/SA/Operation/MeasCalLoad.pdf>

The circuit could easily be breadboarded without much effort, for a cost of about $10. Such measurements don't need to be made frequently, but it's nice to be able to be precise when necessary.

From: Martin
Topic: 8299 Message: 8299

Hi All

I am interested in purchasing a set of the latest revision boards.

The price of the boards through ExpressPCB is great, however postage to AU costs more than the boards, making it expensive (perhaps I have deep pockets and short arms).

I have had a look through the postings and see there have been group buys for the PCB.

Are there spare boards from the previous group buys? Perhaps there is another PCB group buy being considered?

Regards

Marty

8303. replacement to coaxial cavity filter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-08-02 18:34:14 UTC
From: Amos Ku
Topic: 8303 Message: 8303

Hi,

I am new here, but I am kind of innovative type.

I am thinking to build a even smaller kind of everything-in-it version of the wonderful spectrum analyzer (USB based. Software written in C/C++ instead of Liberty Basic, compact..), and I am doing researches on the possibilities and ways to realize my ambitions.

Hopefully, my ambition does not seem too radical...

Looking briefly at the project, I think that replacing coaxial cavity filter may help reducing the entire volume quite a bit. Searching online for bit, do not seem to find any good substitutes. These are what I have researched and tried:

1. Try to find a pair of high pass filter and low pass filter. But nothing can get closer to 2MHz pass band. The closet match now is 20MHz.

2. My RF friend suggested using RF resonantor. Do not know how to design one yet.

3. Searched research papers in components substituting coaxial cavity. Not very fruitful so far.

Has any long-timer and experienced RF engineers in the group here thought about this question and found something useful? Would you please share with me your experience?

The board layouts are in ExpressPCB and can be ordered through them. I think they are posted as a complete panel somewhere; maybe Bob Fish knows?

From: Sam
Topic: 8303 Message: 8306

Some random thoughts:

The critical features of the cavity filter are reasonable loss and the ability to reject the image frequency. The latter means that it must have good rejection at the center frequency plus two times the second IF frequency. With IF2 near 10.7 MHz, the cavity filter must reject well (say, 90 dB) at 21.4 MHz from center. You can make the cavity filter's job a lot easier by using a broader IF2, such as 21.4 MHz. You would then need to find a supply of RBW filters at that frequency, or crystals at that frequency with which you can design your own filters.

There are apparently surplus avionics filters available somewhere in the 1-1.1 GHz range, but I have no idea of their performance.

It would be feasible to use an LO2 that is about 10% higher (requires some changes to PLO2), which would reduce the cavity filter length by 10%.

If you have machining capability, a box-shaped interdigital filter might do the trick. In such a filter, coupling is direct from resonator to resonator so you avoid a bunch of coupling loops. A similar concept, the comb filter, can be built with somewhat downsized resonators (about 2/3 normal length), if you add piston tuning caps at the ends.

Sam,

After I got the pcb's for this SA, I had second thoughts about the 1-1.1GHz filter for the same reasons you have.

So I deserted the "pure" design and made a mixed batch of "Sam's SA" and the "SA53MV SA". That brought up the filter to 2.1GHZ. There are (was) plenty surplus on that band and I found a rather neat one for small money. Problem solved.

I got me a CNC milling machine from Lumenlab.com, Charlotteville, and can machine alu parts for filters etc.

If you want me to, and produce a drawing, I can make a CAM file and machine a sample or two. The design constraints are, max 2" high and 19" by 19" in X and Y.

I have a couple of VNWA's in the shack, one "commercial USB" version and one early prototype I got when I designed the PCB for Tom's VNWA. 1GHz is measured with good precision. So I should be able to tune the filter with ease.

I also have a different VNWA xtal so I have a wee bit better precision and stability than you usually have from the VNWA.

Just pop me an email if you want me to have a go at this.

Cheers

Dan, M0DFI

8310. Re: [spectrumanalyzer] replacement to coaxial cavity filter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-08-03 01:31:57 UTC
From: Phil Harman
Topic: 8303 Message: 8310

Hi Amos,

I have had success with an alternative to a cavity filter. I use a couple of TOKO 6DFC 1.030GHz Dielectric filters.

Since the skirt selectivity, even with two cascaded filters, is not adequate for a 10.7MHz second IF I increased this to 96MHz.

There are a number of low cost and high performance SAW filters available at 96MHz and I used an RFM SF2135A.

You could then further mix this to 10.7MHz - in my case I used an ADC on its first alias to directly digitise the 96MHz IF and did the filtering digitally.

The front end closely follows Scotty's original design. You can find more details regarding the design here:

<http://openhpsdr.org/wiki/index.php?title=CYCLOPS>

The project has stalled for a number of years due to work on other projects and a problem with high noise sidebands on the two local oscillators. However, we have recently re-started to project and appear to have found the cause of the noise.

In any case there is no problem with either the Dielectric or SAW filters.

Regards

Phil...VK6APH

From: Amos Ku
Topic: 8312 Message: 8312

I have been thinking about using DSP techniques to FFT the incoming signals. This may help to eliminate the need to have some of the mixers/filter. Not sure if anyone has thought about this or tried.

G'day,

an alternative to the home built coaxial cavity filter is to use filters from avionics IFF transponders. I've retuned a filter and was able to get it within specifications.

From: william sprowls
Topic: 8299 Message: 8314

The full panel of boards is Rev E and can be found on the web page:
http://scottyspectrumanalyzer.com/msaexpress.html

The link to the actual panel is:
http://scottyspectrumanalyzer.com/slim/expressfiles/expressfull_reve.pcb

This was my combo panel and does not include any of Sam's modules.

Hi Guys,

I had Scotty merge the individual boards into one big layout in PCB
Express for me, so I wouldn't screw it up. But it wasn't just the
boards required for

one SA/TG/VNA it had several other boards added as well. Mixers,
PDM's, Calibration sources, levelers etc. I had to cut them apart
before I sold them. The trouble is

I had a hard disk crash here recently and alot of my stuff wasn't
backed up so I lost it. My wife has me on a weekly back up routine
so it happen to me again.

But, I digress, I will look around and see if I have those files on
a disk or flash drive. But like I said it was for a much larger
collection of boards than just the basic package.

Somebody that is good with PCB Express should merge the individual
board files into a panel for the basic MSA etc. and have somebody
double check it before you order it.

Bob

The board layouts are in ExpressPCB and can be ordered
through them. I think they are posted as a complete panel
somewhere; maybe Bob Fish knows?

Cheerio Berndt,

I am not familiar with avionics IFF transponders.

Would you please give me a hint on with filters, such as part number, website...?

Amos

Subject: Re: [spectrumanalyzer] replacement to coaxial cavity filter

G'day,

an alternative to the home built coaxial cavity filter is to use filters from
avionics IFF transponders. I've retuned a filter and was able to get it within
specifications.

G'day Amos,

No partnumbers, but some models are listed below.

ARC Cessna RT359A
Collins TDR-950
King Radio KT76, KT76A, KT78
Narco AT50A, AT150

These are the more common models found in general avionation.

Most require modifications such fitting suitable connectors, removal of mixer diode etc, but all this is relatively straight forward.

I see now.

Looks like this is an expansive option.

I was thinking if I can combine some ready to go parts from companies such as Mini-Circuits to achieve same kind of rejection and selectivity or some other methods.

Hello Amos;

Many of these old transponders are sitting in junk
boxes for want of replacement transmitter cavities.
with low output or dead peanut tubes in them.

Expect to pay 50 bucks or less for what you are
wanting. The ARC and Narco units are small silver
plated assemblies, easy to use. Watch out for
oxidation between the top cover and the lower
part of the assembly, I usually clean this area with a
pencil eraser. If the 2-56 threads are stripped on
the lower part of the assembly just use a longer
screw and put a nut on it. This compressive force
on the joint is very important to keep the signal
loss to a minimum.

The King KT76 -76A 78 78A are castings and are
significantly bigger than the Narco and ARC. If you
end up with one of these units contact me and I will
give you more information.

Regards;

Greg

8320. Replacing Coaxial Cavity Filters - Different Approaching

Yahoo group: spectrumanalyzer (2011)
Date: 2011-08-03 18:42:01 UTC
From: Amos Ku
Topic: 8320 Message: 8320

Thanks for all the hints about using avionic filters. I will definitely searching for these parts.

Just curious if I can do this:

Using a bandpass filter at 1GHz. After down-conversion, I try using a higher Q bandpass filter at lower frequency, a range where I can easily find or make high Q filters.

Since the coaxial cavity filter is there to reject unwanted aliases and select the signals we want, I think having that done in multi-stages may also work.

Of course, more parts may require larger space, but at least, I can find ways to pack them up in the final enclosure. Having a Coaxial Cavity filters does not seen to be very flexible, mechanical wise. There are very limited ways that I can place the volume.

Not sure if anyone has tried this before....

8321. Re: Replacing Coaxial Cavity Filters - Different Approaching

The IF2 signal is produced by mixing LO2 (1024 MHz) with the cavity filter output; if that output contains 1013.3 MHz, then mixer 2 output will contain 10.7 MHz. Unfortunately, if the cavity filter output contains 1034.7 MHz, the mixer 2 output will also produce 10.7 MHz. Once that 10.7 MHz IF2 signal is produced, there is no way to look back to see whether it came from the source we wanted. And no amount of filtering of IF2 can get rid of the unwanted IF2 signal, which is indistinguishable from the desired IF2 signal.

Therefore, the cavity filter must severely attenuate at 1034.7 MHz, which is 21.4 MHz (more generally, 2*IF2) above the center frequency. That is called image rejection and is the key job of the cavity filter. If it fails, then a strong input signal at, say, 100 MHz will show up at that frequency but will also show up 21.4 MHz away from there. (The ghost appears below the real image, unless I've gotten myself confused.) If you don't get the needed attenuation, increasing the IF2 frequency may solve the problem by putting the image frequency further from the filter center. Changing to a 21.4 MHz IF2 can make a huge difference.

That ghost image will be weaker than the true image by the amount of the attenuation in the cavity filter, so if the cavity filter attenuates 1034.7 MHz by 60 dB more than the center frequency, then the ghost image will be 60 dB lower than the main image. If you assume that you only need "perfection" with signals of -15 dB or lower, and if your noise floor is at -105 dBm, you need the cavity filter to attenuate 1034.7 MHz by at least 90 dB relative to the center frequency attenuation, in order to make the ghost image invisible. You could get by with less attenuation if you were willing to put up with some low level artifacts from strong input signals. But you will certainly want at least 80 dB.

I see.

Since imaging rejection is the key here, I think, then, one of alternatives is to have the signals all go through some kind of A/D processing and have the digital signal processing circuit to display the entire spectrum. When we first enter the center frequency, and then, depends on the span, we can let the system to scan enough bandwidth to display all the signals within the span. This way, we do not need ever to worry about which one is the true image or the alias because only very limited mixing will be probably needed.

True, but it is much more cost effective to digitize after the cavity filter, and probably after mixer 2, where you have to worry about tens of MHz, rather than directly digitizing the input signal, where you have to worry about several GHz. So you would still rely on the cavity filter for image rejection. BUT, that makes it relatively simple to use a higher IF2, since it would be implemented in software at any desired bandwidth. The higher IF2 in turn makes good image rejection easier.

Also, in the digitization process, you have to worry about the entire bandwidth of signals reaching the ADC, not just the "span" that you want to display. Otherwise, out-of-span signals will be aliased into the span and create a mess.

will show up at that frequency but will also show up 21.4 MHz away from there. (The ghost appears below the real image, unless I've gotten myself confused.) If you don't get the needed attenuation, increasing the IF2 frequency may solve the problem by putting the image frequency further from the filter center. Changing to a 21.4 MHz IF2 can make a huge difference.
>
> That ghost image will be weaker than the true image by the amount of the attenuation in the cavity filter, so if the cavity filter attenuates 1034.7 MHz by 60 dB more than the center frequency, then the ghost image will be 60 dB lower than the main image. If you assume that you only need "perfection" with signals of -15 dB or lower, and if your noise floor is at -105 dBm, you need the cavity filter to attenuate 1034.7 MHz by at least 90 dB relative to the center frequency attenuation, in order to make the ghost image invisible. You could get by with less attenuation if you were willing to put up with some low level artifacts from strong input signals. But you will certainly want at least 80 dB.

I see.

No wonder those RF spectrum analyzers are SO expansive. I saw one time that a down converter costing $999. I think it is probably a space vs. cost kind of deal.

True, but it is much more cost effective to digitize after the cavity filter, and probably after mixer 2, where you have to worry about tens of MHz, rather than directly digitizing the input signal, where you have to worry about several GHz. So you would still rely on the cavity filter for image rejection. BUT, that makes it relatively simple to use a higher IF2, since it would be implemented in software at any desired bandwidth. The higher IF2 in turn makes good image rejection easier.

Also, in the digitization process, you have to worry about the entire bandwidth of signals reaching the ADC, not just the "span" that you want to display. Otherwise, out-of-span signals will be aliased into the span and create a mess.

Sam W.

>
> I see.
>
> Since imaging rejection is the key here, I think, then, one of alternatives is to have the signals all go through some kind of A/D processing and have the digital signal processing circuit to display the entire spectrum. When we first enter the center frequency, and then, depends on the span, we can let the system to scan enough bandwidth to display all the signals within the span. This way, we do not need ever to worry about which one is the true image or the alias because only very limited mixing will be probably needed.

> The IF2 signal is produced by mixing LO2 (1024 MHz) with the cavity filter output; if that output contains 1013.3 MHz, then mixer 2 output will contain 10.7 MHz. Unfortunately, if the cavity filter output contains 1034.7 MHz, the mixer 2 output will also produce 10.7 MHz. Once that 10.7 MHz IF2 signal is produced, there is no way to look back to see whether it came from the source we wanted. And no amount of filtering of IF2 can get rid of the unwanted IF2 signal, which is indistinguishable from the desired IF2 signal.

PLO3 is always up. Other than to simplify the code is there a good reason? The problem I have is that, while IN SA MODE, if I leave the TG connected to the SA input , I get crosstalk from PLO3. In my humble opinion, PLO3 should not be active at all in SA mode.

Yes, if the VCO had a disable pin, it would be a good idea to disable it when it is not needed. Unfortunately, it doesn't.

In pure SA mode, why would you have the TG attached to the input? If you want to use the TG, you need PLO3.

Well... If I forget to disconnect the cable after being in TG mode I get
strange things that shouldn't be there. it takes a while to figure it out,
that's all.

Hi Jim,
 I thought long and hard about that when the Tracking Generator was in conception. To be effective, the two RF outputs of PLO 3 must go to "zero" or to at least, a low enough level so as not to interfere with the other SA components. Turning off the VCO 3 would be the best way to do it. This would require switching the power to the VCO (on-off).
 My thoughts were that the extra real estate and component count didn't justify it. Just commanding the PLO 3 to some out-of-the-way frequency was easiest. In the SA Mode, the TG output is never connected to anything, so interference is at its minimum.
 Now that the original -5 volts is no longer used in the PLO module, there is some room to play. We can do this with software and some active component but the really easy way to control the VCO voltage is to:
1. Inside the module, cut the +10v trace between R28/C28 and U5.
2. Tie P1-7 to the input of U5.
3. Add a .01 uf and a 10 ufd from P1-7 to ground for RFI supression.
4. Add an On-Off switch to your MSA.
5. Tie one pole to the +10v distribution on the Control Board
6. Tie the other pole to PLO 3, P1-7.
You can now turn the TG (Sig Gen) on and off.
Scotty

That switch could be handled from software. Also I would add a panel LED to show the TG as running.

There is an alternative approach that can be used when FFT filtering of the signal is used that removes the need for a high IF and narrow filters.

That is to deliberately create an image signal and remove it in software.

For example, if we use a single IF at say 10.7MHz with a wanted signal at say 100MHz we can use a LO of either 110.7MHz or 89.3MHz. Both will mix the 100MHz signal to 10.7MHz where we use an ADC, FFT and save the results.

So we do two measure measurements with two LO frequencies - if the results are the same using either LO then we conclude the samples are valid and display them.

When using the 110.7MHz LO a signal at 121.4MHz will also produce a signal at 10.7MHz. But this will not be present when the LO is moved to 89.3MHz. Similarly with the LO at 89.3MHz then a signal at 78.6MHz will produce a signal at 10.7MHz. Again this will not be present when using the 110.7MHz LO.

Only when both LOs give 'similar' results is the raw data displayed. If a signal does not appear when using both LOs then that signal is digitally subtracted from the signal that is displayed.

This is a very simplistic explanation - in practice the 'devil is in the software' but there is at least one commercial SA that successfully uses this technique.

From: William Dillon
Topic: 8312 Message: 8331

I've been considering this also.

My current line of thinking (I will try with my kit when it gets working well enough) is to split the signal coming from the log detector to the phase detector (should be the 10.7 Mhz IF with constant amplitude) and install a off-the-shelf SDR (software defined radio) kit. Many of these work quite well at 10Mhz. The idea is that they down-convert this IF (using sampling) to DC. The I and Q (in phase and 90 degrees out of phase) can be used to demodulate any signals present. The limitation of this system is the bandwidth of the output. Typically, people plug these into sound cards, setting the bandwidth at 48kHz (before anyone invokes nyquist, you get the full bandwidth because there is an I and Q). It is a good idea to low-pass filter the baseband to ensure that you don't get aliasing from higher frequencies. I've also considered a design with a 2 M sample/second ADC with a USB full-speed interface, but that's way out there.

Anyway, sorry for the ramble.

8333. Re: panel of boards

Yahoo group: spectrumanalyzer (2011)
Date: 2011-08-04 10:58:37 UTC
From: Martin
Topic: 8299 Message: 8333

Hi again All

Thanks very much to the people who have replied, it is great to see a group so active. I have been away for the last couple of days, please excuse my late reply.

There were heaps of replies both on and off the group, in response to the questions about the pricing ...

I emailed ExpressPCB who advised there is no other shipping option other than the one (3 day delivery) offered in the software.

The price of the boards looks great, as do the shipping cost to the US, however at around $60USD for 1 set minboards (3 miniboards in total) to Australia, on top of the manufacture cost (around $50USD) it makes this PCB option an expensive exercise.

And thanks to those who pointed out the location of the panels online and the many other offers of assistance.

Many thanks, regards

Marty

8334. Re: Why is PLO3 up on SA mode?

Yahoo group: spectrumanalyzer (2011)
Date: 2011-08-04 12:18:15 UTC
From: Sam
Topic: 8325 Message: 8334

I still don't see the problem that would be solved. If the problem is that the TG was accidentally left attached to the input when you switched to SA mode, there is a more obvious problem: you're trying to look at SA signals from an external signal source that you forgot to attach.

The interference in SA mode when the TG is not connected amounts to a few spurs that can be moved/eliminated by changing the SG frequency. The software could flip a bit when in SA mode that the user could connect to a PLO3 switch if desired, but we would have to dedicate a latch bit for that purpose. We do have a largely unused latch, which I think was reserved for parallel DDS control. I doubt anyone would do that at this point, so maybe we have bits to play with.

Of course, if PLO3 is turned off in SA mode, then the Signal Generator could not be used unless we provide an override that lets the user turn it back on.

Sam W.

From: Sam
Topic: 8299 Message: 8335

Ah, so it is the overnight delivery that jacks up the cost. Maybe a non-Miniboard order would be more cost effective because it lets you select other delivery options (I think). A full set of boards would require several Miniboard orders anyway. Other options let you order all the boards in one big panel (which you would have to cut apart).

8336. Re: Measuring Calibration Loads

Yahoo group: spectrumanalyzer (2011)
Date: 2011-08-04 13:12:31 UTC
From: Sam
Topic: 8298 Message: 8336

I updated the document with Appendix C, showing some test results. I used a 4 1/2 digit meter to see what the max potential accuracy would be, and it appears to be 0.05% or better. I figure the lower accuracy and resolution of a 3 1/2 digit meter would still give resistance accuracy of 0.1% or better using the circuit described in the document.

With 0.1% accuracy, you could use a commercial termination as a load, rather than homemade loads with 0.1% resistors. The latter still have a place, but they are a bit more fragile. As long as you tell the MSA what the load resistance is, you should get good results. You also need to estimate the internal delay, though error in that estimate is not a significant factor if the resistance is not too far from 50 ohms. I have collections of several brands of SMA terminations, which I bought on eBay knowing that their VSWR specs were good. I found two that are almost exactly 50 ohms, and many that are within 0.2 ohms of 50 ohms. In fact, to measure something several ohms from 50 I had to use a 14 dB attenuator with its end open or shorted.

On the other hand, my collection of BNC terminations were mostly several ohms from 50. Nothing associated with BNC seems very precise.

8337. Re: [spectrumanalyzer] Another spectrum analyzer idea to reduce the RF circuitry

Yahoo group: spectrumanalyzer (2011)
Date: 2011-08-04 13:16:52 UTC
From: william sprowls
Topic: 8312 Message: 8337

Hi William and All,
First off, I don't consider discussions of any spectrum analyzer system "rambling". This is probably a good place to bring up ideas.
Here is my two cents worth:
There are two categories of SA's, analog and digital. Analogs have simple topologies but require significant attention to layouts, crosstalk, interference, spurious, etc. Digital topologies seem even simpler, but are deceiving due to the software required to make them work.
I can assure you that the conception and design of the MSA was not done without knowledge of DSP techniques. My goal was a high quality, yet inexpensive spectrum analyzer. In 2000, DSP was cumbersome and very expensive. Not conducive to home construction. Now, in 2011, it is much simpler and very affordable. However, the software is no less extensive. I can safely say that it would be impossible using Liberty Basic. For this reason I have no plans to convert or retrofit the MSA into a DSP environment.
With that said, there is good reason for group members to support anyone who would like to pursue a DSP based analyzer.

I will run some tests in SA mode with and without TG power.
Obviously I'll publish the results to the group.
If there is any indication of a difference (and a few spurs are sufficient)
I will try a manual switch or even P1D7 (the third unused bit for the RBW
switch, PB7 in USB) since it is available.

These board are not as same as Panel Rev E, I hope the changes won't cause RF leakage and create toubles.
I have done a 10.7MHz RBW filter, the rejection difference between a ' RF tight' and non-RF tight, can be 20dB (from 60 to 80dB), refer to the photo here:
http://groups.yahoo.com/group/spectrumanalyzer/photos/album/608125393/pic/537353207/view?picmode=&mode=tn&order=ordinal&start=81&count=20&dir=asc

Hi Scotty,

I am more conscious of the trade-offs between analog and digital analyzers every day... I've been looking around for a SA at work, there is a huge gulf in the spec's between them. The ATTEN 6011 is a good example of a low-cost and low-spec'd digital analyzer. However, my suggestion is only intended as an addition to the already functioning MSA/VNA. I would love to be able to perform all the same calibrated analysis that is possible, but also tune into signals and demodulate them. I think that would be really, really cool. That's really the idea behind my suggestion. I'm working on this idea in my spare, spare time. There's even less of that than my spare time, so I don't see anything happening too soon with it, but I'll let people know if I get anywhere.

From: Dan Andersson
Topic: 8312 Message: 8342

Will,

The cheapest and fastest way to achieve demodulation etc, is to use a SDR setup on the SA output so you can display the demodulated signal on a PC.

I would expect a Linux box with GnuRadio to be the most flexible alternative or why not just use any of the available SDR softwares.

Most digital SA's that fit in a non-defense sized wallet "should be avoided" - bad use of wording but still, if you do hi tech work where you really need to know what you see is true.

It's cheaper to achieve that with an analog SA, at least for now.

There is a reason Agilent et Al charges the prices they do.

I agree with Jim. SDR is an interesting topic that we might want to try. Several companies already have the SOC contains the L band tuner with SDR, it capture the whole band and create multi digital tuners.

Hi Guys,
I too have thought about how cool it would be to have a 0 to 3GHZ general coverage receiver using the IF out of the SA. When I was a bench tech, I used to use an HP spectrum analyzer to listen to the radio while I was working on other things.
My boss used to compliment me on my using the worlds most expensive AM radio. (I am not sure it was a compliment)
To use SDR, you would need two applications running at once on your PC, no biggie of course, but you would have to change screens to change frequency or filters, audio level etc.
If you don't absolutely have to have all those fancy DSP filters and just want to demodulate what you see on your SA. There may be an analog solution as well . Something like this might do the job.

http://www.kangaus.com/micror2.htm

It could be a tabletop, single board, back end for your SA/general coverage receiver. A few minor component changes to move the receive frequency from 7MHZ to 10.7MHZ. It can also be made to demodulate AM, Narrow band FM or the CW/SSB it is designed for currently. These Direct conversion receivers designed by Rick Campbell have a reputation for superb audio and high performance. He was one of the authors of "Experimental Methods In RF Design" a very popular book amongst homebrewers. A whole chapter or two is dedicated to this type of DC receiver. A google rearch for Rick Campbell KK7B should return documentation of several of these type of receivers that he has designed. Not being an engineer, I am probably overlooking some difficulties in using this setup. but maybe it's as simple as it looks.

Have Fun,

Bob

Look at what I have just found:

http://www.jpier.org/PIER/pier78/25.07091401.Hasan.N.pdf.

The title of this article is:
NOVEL MICROSTRIP HAIRPINLINE NARROWBAND BANDPASS FILTER USING VIA GROUND HOLES.
 Wow! If I can tune this filter to that of the coaxial cavity filter. I can greatly reduce the room for a coaxial cavity filter!

From: Berndt Josef Wulf <wulf@...>

Subject: Re: [spectrumanalyzer] replacement to coaxial cavity filter

G'day Amos,

No partnumbers, but some models are listed below.

ARC Cessna RT359A
Collins TDR-950
King Radio KT76, KT76A, KT78
Narco AT50A, AT150

These are the more common models found in general avionation.

Most require modifications such fitting suitable connectors, removal of mixer diode etc, but all this is relatively straight forward.

8347. Re: [spectrumanalyzer] replacement to coaxial cavity filter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-08-04 22:34:12 UTC
From: Amos Ku
Topic: 8303 Message: 8347

One question:

I am not very sure what the definition of 2MHz bandwidth for the coaxial cavity filter is. Usually, people define bandwidth as defined at -3dB points. It looks like that is what this coaxial cavity filter requirement is about. However, what is the requirement for the other parts of the pass band? It looks like the decay rate is going very sharp. But how sharp the filter should be in order to do sufficiently good image rejection that we discussed?

Subject: Re: [spectrumanalyzer] replacement to coaxial cavity filter

G'day Amos,

No partnumbers, but some models are listed below.

ARC Cessna RT359A
Collins TDR-950
King Radio KT76, KT76A, KT78
Narco AT50A, AT150

These are the more common models found in general avionation.

Most require modifications such fitting suitable connectors, removal of mixer diode etc, but all this is relatively straight forward.

From: Dan Andersson
Topic: 8303 Message: 8348

Amos,

The article you refer to is nothing new. Look for an article from 1st quarter 1989 "How To Build a Stripline Filter". It's stored at www.hparchive.com

Normally, a 1GHz stripline filter is rather large. But by grounding the endstubs, you almost half the frequency of the filter without any other changes.

If you don't have the article, mail me directly. This artcle gives the math for the filter design so you can't really miss.

The grounded stripline filter is less susceptive to detune when mounted in a metal box. The open stripline filter is more sensitive to environmental capacitances.

USE ONLY 0.8mm FR4.

Rogers and alikes is a Royal waste of money for only 1GHz, save it for 3+ GHz.

Do not use 1.0 or 1.5mm FR4. If you only have 1.5mm, don't really bother as even 1GHz is a border case.

You really have to mount the filters in proper boxes!

Another good article is "The Design, Fabrication and Measurement of Microstrip Filter and Coupler Circuits" by Dana Brady at CA Wireless, Inc.
It was published in July 2002 "High Frequency Electronics" and is Copyrighted 2002 by Sumit Technical Media, LLC

Many articles refer to Agilent ADS. It's a nice piece of software but for most applications, you can use QUCS instead. The layouit and syntax is almost 100% equal to ADS but it's free and open source. QUCS is available both on Linux and on Windooze.

Again, I have both articles but will not drop them to the group. You need tp email me directly for a non-commercial priavte copy.
(One day it might be me or you that creates something we want to copyright, so let us respect theirs)

Interesting stuff. The article is at:
<http://www.hparchive.com/Bench_Briefs/HP-Bench-Briefs-1989-01-03.pdf>
Seems to be fairly broad-bandwidth, though.

From: Amos Ku
Topic: 8303 Message: 8350

Thanks.

I am not trying to persuade anyone to deviate from Scotty's design. His design is wonderful and inexpensive. This is very good for the hobbyists like people in this group.

I am just trying to be a little out-of-ordinarily ambitious and trying everything I can to push the final design of mine close to the professional level, while maintain the simplicity of original design idea.

As I can see, many things can be done to improve the entire design. I am just starting to try out different things.

Amos

Keep on Amos. That microstrip research paper that you unearthed
looks promissing.
Certainly is not a rehash and being published in 2008 is not "old stuff".

8352. Re: replacement to coaxial cavity filter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-08-05 13:55:34 UTC
From: inlinebeginner
Topic: 8303 Message: 8352

I like what Amos is doing. To make the impossible to be possible, we really need this kind of topic and brainstorm. Even we fail we still could learn a lot from his tries.
The cavity filter's transient band has to be less than 2*IF2 (about 21.4MHz for a 10.7MHz RBW filter) and the rejection at +2*IF2 (off center freq) needs about 80 to 105dB, as Sam said. This requirement seems to be very critical for a microstripline filter, but we still can try how small its transient band can be. Once we have that number, we might want to add one more IF between IF1 to IF2 (maybe we can call it IF1a).
If we look at the structure of early HP 8558B, a 1.5G SA, it has IF1=2050MHz, IF2=301.4 and IF3=21.4MHz. The reason it uses IF2= 301.4MHz might be just to provide a wider transient band for cavity filter and get better image frequency rejection for mixer2. Once the frequency is dropped to 301.4MHz, the mixer3's image freq rejection becomes easier. i.e a 301.4MHz LPF or BPF can be much easier to implement a transient band of 2*21.4=42.8MHz than a 2050MHz filter.
Adding one more mix/PLO into current MSA, may not cost much. A combo IC (of mixer, PLL, VCO) RFFC2071 only cost less than $30, with at least 90dB phase noise.
If we use HP8558's IF2 number, 301.4MHz, the cavity filter transient band can be 602.8MHz, I think it is possible to implement this number in a 1013.7MHz LPF or BPF microstrip line filte or we can use other filters in casecade.

Thanks
Lin

8353. Re: [spectrumanalyzer] Re: replacement to coaxial cavity filter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-08-05 14:16:17 UTC
From: Dan Andersson
Topic: 8303 Message: 8353

Lin,

Cascading is fine as long as the insertion loss is low.
This is not always the case with stripline filters.

8354. Re: replacement to coaxial cavity filter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-08-05 17:42:59 UTC
From: inlinebeginner
Topic: 8303 Message: 8354

If you look at Digikey, under ceramic filter, you can found this:
http://media.digikey.com/pdf/Data%20Sheets/CTS%20Corporation%20PDFs/KFF6402A.pdf

center frequency 1.09G , 6MHz BW, 45dB rejection at +45MHz. 2 dB insertion loss;
If we can use 3 in cascade, the insertion loss would be the same as current cavity filter, while the rejection at 40MHz should be 80dB or higher. The BW would drop to 4 or 3MHz, similar to curren cavity filter (2MHz).
The advantage: small size 34x8 mm each; if we can use 25MHz crystal filter as IF2.
Disadvantage: Expensive $50 each.

What we are discussing is only for SA, a portable SA, not including the VNA.

Lin

8355. Re: [spectrumanalyzer] Re: replacement to coaxial cavity filter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-08-05 17:51:04 UTC
From: Dan Andersson
Topic: 8303 Message: 8355

Check the file "Recipes_for_Printed_Hairpin_Filters.pdf"

I just started the math on a 1013MHz hairpin filter.

I hope to have it ready for PCB fab in an hour or so unless it's to cold and dark in my garage. I'll make the CAM file and mill the PCB today or tomorrow. That should be a starting point as I can just push another button for more than 1 filter.

8356. Re: [spectrumanalyzer] Re: replacement to coaxial cavity filter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-08-05 17:52:59 UTC
From: Amos Ku
Topic: 8303 Message: 8356

Wow! What a good news! See what technological advances can help to improve the life of our hobbyists.

Lin,

Thank you very much for the info. Even $50 is fine for me at this point.

Subject: [spectrumanalyzer] Re: replacement to coaxial cavity filter

If you look at Digikey, under ceramic filter, you can found this:
http://media.digikey.com/pdf/Data%20Sheets/CTS%20Corporation%20PDFs/KFF6402A.pdf

center frequency 1.09G , 6MHz BW, 45dB rejection at +45MHz. 2 dB insertion loss;
If we can use 3 in cascade, the insertion loss would be the same as current cavity filter, while the rejection at 40MHz should be 80dB or higher. The BW would drop to 4 or 3MHz, similar to curren cavity filter (2MHz).
The advantage: small size 34x8 mm each; if we can use 25MHz crystal filter as IF2.
Disadvantage: Expensive $50 each.

What we are discussing is only for SA, a portable SA, not including the VNA.

Lin

From: William Dillon
Topic: 8303 Message: 8357

The price is surely a significant disadvantage. The cost in parts (surely not time) for 10 cavity filters would be less than one 3-filter cascade using this part.

Subject: Re: [spectrumanalyzer] Re: replacement to coaxial cavity filter

Check the file "Recipes_for_Printed_Hairpin_Filters.pdf"

I just started the math on a 1013MHz hairpin filter.

I hope to have it ready for PCB fab in an hour or so unless it's to cold and dark in my garage. I'll make the CAM file and mill the PCB today or tomorrow. That should be a starting point as I can just push another button for more than 1 filter.

8359. Re: [spectrumanalyzer] replacement to coaxial cavity filter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-08-05 18:03:07 UTC
From: Amos Ku
Topic: 8303 Message: 8359

William,

Right. I think at this point. I just have a little spare to spend on. I think soon or later we will find a cheaper alternative. Just need to keep trying and searching. We will find a way.

Amos

Subject: Re: [spectrumanalyzer] replacement to coaxial cavity filter

The price is surely a significant disadvantage. The cost in parts (surely not time) for 10 cavity filters would be less than one 3-filter cascade using this part.

8360. Re: [spectrumanalyzer] Re: replacement to coaxial cavity filter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-08-05 18:40:19 UTC
From: Amos Ku
Topic: 8303 Message: 8360

The coaxial cavity filter has only 2.5MHz. Not sure if 6MHz BW will be still in the okay range for image rejection.

From: inlinebeginner <inlinebeginner@...>

Subject: [spectrumanalyzer] Re: replacement to coaxial cavity filter

If you look at Digikey, under ceramic filter, you can found this:
http://media.digikey.com/pdf/Data%20Sheets/CTS%20Corporation%20PDFs/KFF6402A.pdf

center frequency 1.09G , 6MHz BW, 45dB rejection at +45MHz. 2 dB insertion loss;
If we can use 3 in cascade, the insertion loss would be the same as current cavity filter, while the rejection at 40MHz should be 80dB or higher. The BW would drop to 4 or 3MHz, similar to curren cavity filter (2MHz).
The advantage: small size 34x8 mm each; if we can use 25MHz crystal filter as IF2.
Disadvantage: Expensive $50 each.

What we are discussing is only for SA, a portable SA, not including the VNA.

8361. Re: replacement to coaxial cavity filter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-08-05 19:02:09 UTC
From: inlinebeginner
Topic: 8303 Message: 8361

The image rejection may not relate to cavity BW, it depends upon the cavity filter rejection at 2*IF2 away from center frequency.
If you can meet the image rejection, it might be ok for a 6MHz BW cavity filter, because the widest RBW filter is normally less than 1MHz.
Lin

Yahoo! Thanks. What a relief.

Okay. I think my problem is solved for the time being. I am trying to attack the next....

Subject: [spectrumanalyzer] Re: replacement to coaxial cavity filter

The image rejection may not relate to cavity BW, it depends upon the cavity filter rejection at 2*IF2 away from center frequency.
If you can meet the image rejection, it might be ok for a 6MHz BW cavity filter, because the widest RBW filter is normally less than 1MHz.
Lin

8363. Expanding the bandwith to 10GHz or 20GHz

Yahoo group: spectrumanalyzer (2011)
Date: 2011-08-05 19:26:06 UTC
From: Amos Ku
Topic: 8363 Message: 8363

Hi all,

I am starting to attack my next problem. Hope I have not disturbed anyone's peace of mind near weekend.

I have been thinking if I can expand this spectrum analyzer to 10GHz, or if possible, to 20 GHz.

From my limited experience and knowledge, it seems that there have been attempts to work on the 2GHz and 3GHz options.

I am thinking if there is a way, just the way it was for DC to 1GHz option before, to create a different structure that will enable to use this SA from DC (well, some low frequencies for those experienced RF gurus.) to 10GHz directly.

Perhaps, just use another narrow bandwidth filter as optional path for people to switch to. Or, even better, having a single structure that will allow straightway from DC to 20GHz.

Many of my experiments that I wish to do involve observing harmonics and spurious signals at the 10 to 20GHz range. It will be really good if I can build a SA that can have this kind of BW.

Amos,

Many older SA's use Harmonic Converters. These are fairly (actually) simple to build up to 26GHz.

Try S53MV's HC design but with the "Scotty" frequencies.

Dan,

Not sure what you meant. Sorry for my ignorance. I will have to do some study on HC's design, so that I know how to try HC's design and stay with Scotty's frequencies.

Did not have time to read it all. Only briefly scanned the web page.

Looks like this design uses no computer interface/control. Save trouble for writing programs. I will consider it an advantage for people cannot afford to buy even Liberty Basic.

Anyway, sounds like a good design as well. Will need some time to do the reading.

Hi Amos,

I set up the CNC mill for PCB filter milling today and it looked good.

Unfortunately with these computer controlled CNC milling machines - they do
exactly what they are being told to do...

Idiotic orders is sure to give an idiotic result :)

I'll make new drawings today/tomorrow unless I'm hit by to much beer...

8369. Isolation amplifiers

Yahoo group: spectrumanalyzer (2011)
Date: 2011-08-09 14:21:39 UTC
From: jghbeta
Topic: 8369 Message: 8369

An issue that came up during phase calibration has to do with an isolation amplifier at the output of Mixer 3. This amplifier together with another one between PLO2 and Mixer 3 is supposed to cut down leakage to Mixer 2. However, the amplifier cuts off frequencies below 250 Hz. The effect is a sharp dip of the magnitude trace as seen during phase calibration VNA mode which then climbs up to reach its normal output level after300-400 MHz.. I removed the amplifier without any apparent detrimental effects on the leakage. The trace is back to normal: a fairly flat line from 0 to 1000 MHz at around -20 dBm.

8370. USB update

Yahoo group: spectrumanalyzer (2011)
Date: 2011-08-09 14:44:19 UTC
From: jghbeta
Topic: 6514 Message: 8370

After a few intensive debugging sessions with the help of Scotty I got my the MSA working with 100% USB interface to my computer. 100% means that I don't use the control board at all. As far as I have been able to determine all functionality is there. The following summarizes what I have learnt and the changes that were required:

1. SOFTWARE. Version 116L does not require any changes to run USB with one exception: if you are using the 4112/4113 charge pumps in any of the PLO's, then a change must be made to the code. It will be incorporated into the next revision by Scotty.

2. USB INTERFACE: I use the EZUSB board with the 128 pin Cypress chip. It is available in eBay. Don't use a 56 pin chip or you will run out of ports. The drivers and instructions were posted to the group by Dave Roberts .

3. MSA HARDWARE MODIFICATIONS: The only changes have to do with the ADC board

a) THE MUN2211 buffers must be changed to 2N7002 FETs. Each one must have a 10K pull down resistor from gate to ground and a 4K7 pull up resistor. A 100pF cap MAY be needed from gate to ground.

b) In order to protect the USB chip ports when the board is not energized and the MSA starts, the power to the 2N7002 pull-up resistors MUST COME from the USB board (3.3 or 5 volts are available). Although the USB chip operates from 3.3 volts, its ports may accept up to 5.5 (I prefer 3.3 myself).

c) The SERCLK and CONVERT lines must be decoupled with 100pF capacitors at the ADC board.

I have prepared a 1.2x2.4 SLIM which includes the ADC and the video switch boards into one and incorporates all the changes described above. If there is any interest I'll do a small group buy. Just let me know.

d) WIRING. Of course, all control wiring (boards PDM, ADC, PLO 1,2, 3, DDS 1, 3 and switches) has to be moved to the USB ports. I will post a wiring diagram in the files area although I believe that Scotty is going to do the same at his site. This sounds like a lot of work but gave the opportunity to clean up my snake's nest.

4. POWER SUPPLY
The conventional power supply at the control board may continue to be used. For sake of neatness I installed Sam W. power supply.

I believe that's all

Jim W1JGH

8371. Re: Isolation amplifiers

From: Sam
Topic: 8369 Message: 8371

Cuts off frequencies below 250 Hz? Do you mean 250 MHz? I don't see how frequencies below 250 Hz would be relevant.

The optional amp on the Mixer 3 output is not really for leakage reduction; it is to improve the return loss of the TG port and to prevent high frequency reflections back into Mixer 3. Such reflections can affect the net signal strength of the TG and thus distort measurements (even at low frequencies), depending on the nature of high frequency reflections from whatever the TG is attached to.

It's frequency coverage depends entirely on coupling capacitors, so it should be easy to handle everything above 100 kHz, or even lower if you want.

Good work. I'm sure a lot of people will find that helpful. Just to clarify for everyone: Jim already confirmed that USB works when wired through the control board. This latest effort allows you to dispense with the control board. If you already have the control board, you may choose to use USB with the control board, but if you are just building, there is no point to using the control board (unless you want it for the power supply). I designed a substitute board that provides +10 and +23V, called the Power Board. Not sure where I posted it.

Jim, any idea as to how the speed of USB compares to the parallel port?

Hi Sam and All,
I don't think Jim H. ever got the USB to Control Board active. But I can answer that question.
As a relative measurement, the sweep time for 400 steps in the Spectrum Analyzer mode:
Parallel LPT to Slim Control Board, 1.84 seconds.
USB to Slim Control Board, 1.91 seconds.
I can simulate the USB Directly to Slims (no control board) and it is essentially the same, 1.89 seconds.
(Using really fast computer, WinXP, and USB2.)
Hardly any difference. However, the "string" commanding that the USB is using is not quite as efficient as it could be. Also there is a minor problem with the "string" structure that I had to circumvent with a tiny hardware change. Right now, the USB will not work with earlier versions of Windows. I will get with Dave on these areas.

Are the USB->SLIM connections still the same?

I designed a PCB assuming the connections in "Controller Hardware.pdf" posted on Aug 18th 2010. I sent the board out to be mfg'd, but haven't gotten it yet. Assuming that it works and is accurately reflects the contents of this document, should it work?

Sam,

What bandwith can you "get away with" when replacing the cavity filter?

I've been running a cople of iterations of milled filters now but with different bandwidths.

My suggestion is to make it 3MHz wide and to make
that the widest IF by bypassing the narrower band
10 MHz filter with a pass through. Other narrower IFs
can be made by adding narrower 10M7 filters in place
of the bypass.

Greg

From: william sprowls
Topic: 6514 Message: 8377

Hi William,
Yes, that document is valid. Since then, proposed modules have been added to the MSA as optional items. These will take up the bits that this document calls "spares". These include:
RF Band Switch for B1/B2/B3
Video Bandwidth Filter
VNA Router Switch
I will update the MSA wiring diagram to include all of the signals. This is what Jim was referring to.
Scotty

Are the USB->SLIM connections still the same?
I designed a PCB assuming the connections in "Controller Hardware.pdf" posted on Aug 18th 2010. I sent the board out to be mfg'd, but haven't gotten it yet. Assuming that it works and is accurately reflects the contents of this document, should it work?

On Aug 9, 2011, at 10:17 AM, william sprowls wrote:

Hi Sam and All,
I don't think Jim H. ever got the USB to Control Board active. But I can answer that question.
As a relative measurement, the sweep time for 400 steps in the Spectrum Analyzer mode:
Parallel LPT to Slim Control Board, 1.84 seconds.
USB to Slim Control Board, 1.91 seconds.
I can simulate the USB Directly to Slims (no control board) and it is essentially the same, 1.89 seconds.
(Using really fast computer, WinXP, and USB2.)
 Hardly any difference. However, the "string" commanding that the USB is using is not quite as efficient as it could be. Also there is a minor problem with the "string" structure that I had to circumvent with a tiny hardware change. Right now, the USB will not work with earlier versions of Windows. I will get with Dave on these areas.

Good work. I'm sure a lot of people will find that helpful. Just to clarify for everyone: Jim already confirmed that USB works when wired through the control board. This latest effort allows you to dispense with the control board. If you already have the control board, you may choose to use USB with the control board, but if you are just building, there is no point to using the control board (unless you want it for the power supply). I designed a substitute board that provides +10 and +23V, called the Power Board. Not sure where I posted it.

Jim, any idea as to how the speed of USB compares to the parallel port?

Dan,
The bandwidth is not important. You would like it as narrow as possible, but not narrower than the widest Resolution Filter you plan to use. Doubtful that you can get a BW of less than 1 MHz, anyway.
 The important specification is that the Image Frequency response must be at least -70 dBc, with -90 dBc as a goal. The more, the better. The present cavity filter is about -110 dBc.
The image frequency will always be:
Fimage = LO2 + Final IF
example: 1024 + 10.7 MHz + 1034.7 MHz

Thanks Scotty.

The board should be here in a few days. I'll do basic testing to make sure I didn't screw anything major up. The minimum number of boards I can order from this factor is 10 (not bad at $2.50/ea). If it looks like they work O.K., I'll have extras. If anyone is interested let me know, off-list is probably best.

Topic: 8375 Message: 8381

We usually talk in terms of a 3 dB bandwidth of 2-3 MHz, but in fact the most important specification is that you get good attenuation (hopefully better than 90 dB) at 2*IF2 above the center frequency. With Scotty's cavity design, the two go together to some extent--if you have a 3 dB bandwidth of 5 MHz you probably won't do well at +2*IF2. But another design might function differently.

Here are some things I recall from experimenting:

If you compare a perfect filter to one that is somewhat overcoupled, the S21 response of the overcoupled filter is shifted upward, but the top hits a ceiling and flattens out. The effect is a significant widening of the 3 dB bandwidth, with only a couple dB effect on attenuation at +2*IF2, so perhaps no harm is done. (An undercoupled filter will have a sharp peak, but the insertion loss will be high (i.e. the top of the peak will not be as high as you want.)

Slight tweaking of the tuning of a resonator can significantly affect the peak, so if you rely entirely on getting the dimensions exactly right, without tuning ability, you are not likely to have much success.

The bandwidth is my main concern right now. The low side is -150 dB down and very steep and that is good for a PCB Intedigital filter. I can intruduce tuning screws in the lid if I need to further finetune the filter. With 10MHz BW, the "quality" of FR4 driblles the centre frequency allover the place between samples.

I'm trying to stay within 80 by 50 mm size so I'm not targeting anything elaborate.

Topic: 8375 Message: 8383

To clarify: Scotty refers to the image frequency at LO2+IF2. The cavity filter center (Fc) is LO2-IF2. So my Fc+2*IF2 is the same as Scotty's LO2+IF2. BTW, I believe the reason the image has that name is that it is the "reflection" of Fc through LO2. Just as an optical image in a mirror is the same distance behind the mirror that the object is in front of the mirror, the image frequency is the same distance above LO2 as the target frequency is below LO2.

Well,

I have better attenuation below the centrefrequency.

To be absolutely frank, I think it will be hard to replace a cavity filter with any PCB based solution.

I'll give the PCB filter some time before I start making a reproducable cavity filter. It's the bandwidth that is the PCB caveat.

I believe a major issue with a PCB solution is that it uses flat resonators. One might think that microstrip lines are wide enough that, even with skin-effect limiting current flow to the (bottom) surface, the resistance would not be too bad. But in microstrip, the same forces that cause skin-effect tend to push the current to the edges of the strip. So the current can't take full advantage of the surface area. That means more resistance, more loss, and wider bandwidths.

The other issue is dielectric loss, which can be alleviated with expensive substrates, but I don't think there is any way around the flat resonator problem. It's hard for a 0.1" wide strip to compete with a 0.25" diameter rod.

Sam
Can we apply your Ampfilter concept to this microstrip line cavity filter? It could compensate the loss, and make more stages.
Lin

An amplifier can compensate for insertion loss, but not for the broadening of filter response that is caused by low Q.

One might think that microstrip lines are wide enough that, even with skin-effect limiting current flow to the (bottom) surface, the resistance would not be too bad. But in microstrip, the same forces that cause skin-effect tend to push the current to the edges of the strip. So the current can't take full advantage of the surface area. That means more resistance, more loss, and wider bandwidths.

Yes, but...

No amplifier in the world can compensate for lost low level signals.

Lost is lost.

Sure, you can run a cooled amplifier to lift up the signals from the noise like
in radio telecope setups but realistacally - no.

Who have a free supply of nitrogen nowadays?

In the amplifilter, the amplifier is in the middle. It can't recover signals lost to the noise in the first half, but it can boost the remaining signals so they don't get lost in the noise in the second half. So it partially saves signals from getting lost. But that is just gravy; its main purpose is to prevent interaction between the two halves, which pretty much eliminates the need for tuning, and eliminates ripple.
Sam W.

So, while we're on the topic of cavity filters...

I've seen some topologies that use a bandpass filter for the desired pass band, and another band pass filter for the desired rejection band. The filter that selects the rejection band is terminated in a dummy load. The idea is to absorb the energy in the rejection band to increase the isolation. I think that the two filters are connected using a coax tee at the input. Does something like that even work?

Good thought. I don't know enough about it to know whether that particular arrangement is feasible, but it certainly is possible to supplement the cavity filter with a band rejection mechanism. The trick would be to do it in a way that makes the overall filter simpler. Perhaps a microstrip band rejection filter would be effective enough that you could get by with a 2- or 3- stage cavity filter. The rejection would have to be modest(30-40 dB?) at 2*IF2 above 1013.3 MHz, without having much effect at 1013.3 MHz. Those requirements don't seem too demanding. Maybe even a "coax stub" could do the trick, if the "coax" were low loss--such as being constructed like a stage of the cavity filter (but no coupling coils would be needed, and maybe the pipes could be smaller diameter).

I built a similar trap filter for 1045 MHz, using a thru line between two SMA connectors, with an open coax (0.141") connected to the line through a 2.5 pF capacitor. The capacitor greatly sharpens the response (and provides some tuning ability), so I got 35 dB attenuation at 1045 MHz but only a couple dB at 1 GHz. Simulations showed that I could do much better with a smaller capacitor if the coax were lower loss.

Conceivably, the fact that the cavity filter return loss will be far from 50 ohms at the image frequency complicates things.

Sam W.

That was definitely a sticking point I thought of (the impedance match). I don't remember the context, but I remember that there was some wizardry related to making the impedances work out correctly such that the insertion loss was low and there weren't reflections from the image.

Sam,

I've been toying with hairpin filters and there is a small possibility it will work.

I will not be able to produce the filter until end of next week so I attach the Gerber and CAM file if anyone else want to have a go while I'm away.

The filter will be difficult for homebrewers due to very(!) high demands on precision. I'm not a friend of hairpin filters but they do have little insertion loss and are very flat.

The 1013MHz is a bit on the low side for these kind of filters.

Have you ever tried toner transfer? From your gerber file, I did not see any connector, where do you connect to? The most left and right copper? FR-4 1.6mm thickness two layer PCB? or top layer only?

Toner transfer? Nahh. Expensive and unreliable

But I have a CNC milling machine with accuracy better than 0.0002" :)
(www.lumenlab.com)

FR4. 0.8mm !!!!!!!!! and two layer of course.

Port 1, left just above the lower end 5 to 10mm up
Port 2, Right just below the UPPER end, 5 to 10mm down

Hi Sam / Scotty

I'm using the compiled 116L while commissioning by MSA. I cannot seem to get the 4112's to command ie no output from U2-2?

I have spent many hours rechecking components & wiring and all voltages etc look ok except the PLO locking. The VCO U4 sits at 800-900MHz whether on sweep or pause. I have the additional resistor added at U2-1.

Also the title bar of the software says 116 ver F not L (completely new install)?

Any help appreciated.

Chris

Hi Cris,
I also noticed the title is incorrect. It didn't get changed in the upgrades.
If all 3 PLO's are not locking, I would tend to believe that the PLO's are not getting the correct command.
Does the AtoD work and give a Magnitude trace on the graph? It may be below -100 dBm so change the Mag scale to look down to -130 dBm. If it does, the LPT is "talking and listening" correctly.

Don't know if this is useful but there is some information on PC board filters here:

http://www.w6pql.com/pc_board_filters.htm

Roderick.

Toner transfer? Nahh. Expensive and unreliable

But I have a CNC milling machine with accuracy better than 0.0002" :)
(www.lumenlab.com)

FR4. 0.8mm !!!!!!!!! and two layer of course.

Port 1, left just above the lower end 5 to 10mm up
Port 2, Right just below the UPPER end, 5 to 10mm down

Hi William

Sorry, I forgot to mention that PLO2 is commanded to 1024 OK. I have check as per the test that all latches on the control board are working. Data, clock & LE lines appear ok on my oscilloscope. The DDS boards are working as per the test procedures. The IF J3 back to ADC are all working fine.

Just PLO1 & 3 will not lock.

Cheers Chris

Hi Chris and All,
The one thing that both PLO 1 and PLO 3 have in common, but different than PLO 2, is that they both require +20v.
Check the op amp, pin 7, for the +20v. Make certain the op amp, pin 4 is at ground. And, this may sound silly, but make certain the op amp is installed correctly. (One builder did flip it 180 degrees during installation).
Troubleshooting the MSA is a fairly easy process for me, since I know it so well. However, doing it using e-mails is tedious. Many group members had stated that they didn't mind witnessing a trouble shooting process, but it is still cumbersome.
When helping Jim H., he suggested I download "Skype" and use it "real time". It worked like a charm. We were able to troubleshoot very quickly. I would suggest that you get Skype, it's free and very easy to use. All you need is a high speed internet connection (DSL or faster) and a microphone connedted to your computer. An added web-cam is icing on the cake. My skype name is wsprowls. Just put me into your contact list and "call" me when you need help.
Scotty

I do think this kit will sell if turned into a complete kit.

However, in order to do that, some more things needed to be done to turn it into a commercial grade.

Try Cash Olsen, he was doing some kitting.

The problem with a kit is you only get the exact number of parts required so when a part pings off the board as you are about to solder it in place, you have no spares and you end up spending hours crawling around on the floor looking for the missing part that is only costs a fraction of a penny / cent.

There are lists of components and Digikey part numbers available on the Yahoo site to help you order. OK, you may end up with a pack of 10 resistors when you only need 2 but they go into the spares box ready for the next project or you can swap or give them to someone else doing a build.

Back at the drawing board again.

I have been browsing the available internet resources on PCB based filters but very few are usable for us normal ham's without a doctorate in maths.

The 1.013GHz frequency is also a problem by being "too low" and that increases the size of some parts of the filters but makes other parts very tight due to the demand for low insertion loss and flatness.

I have a couple of hairpin solutions I will try this weekend. The problem is to design the filrŕers larger than my smallest mill bits.

There are also embarassingly little software help available for actual filter design. The choice seems to be for expensive software or ridicouluosly expensive software.

Luckily, I have access to one of these absurdly priced softwares and I get Gerber files as outputs. So I have a couple of alternatives to mill.

That said:

There are difficulties due to FR4 laminates varying from 4.1 to 4.7 so making more than one filter requires the material to be from the same batch.

Using any of the PCB houses for PCB filters is not as easy as other PCB's. You need a couple of itetations and then it can change because of a different FR4 batch or supplier.

Making the filter 5, 6 or fiftyleven pole makes no difference as it's only the the size that changes. Another important factor is the encapsulation.

They are very quick to mill.

I'll try to design a small footprint filter so I can decide for go or nogo regarding PCB filters and the SA build.

Amongst all othe delayed projecs - Sigh!

Hi Dan,
 I had been in the "business" for many years before computers and software only big corporations could afford. I found that microwave filter engineers specialized in that one thing and very little else. The really good ones could not walk and chew gum at the same time. If their lives depended on reading the color code of a resistor I would have been to many funerals. Even the very best designers had a basket full of rejects before finalizing a design. Don't fret too much, they really are the dark side of engineering.

Hiya Scotty,

Yes, I know what you mean :)

I do have access to some absurdly priced magic software and I get decent results from it almost every time. And yes, some iterations is required every time I do a filter design as the dielectrical constant varies from supplier to supplier and even batch to batch.

I don't even try to do cavity filters, even with the software help. I remember they used to burn these kindof engineers on a stake in Halem as witches and magicians once upon a time)

But the main problem is that if I design (with fiftyleven iterations) a working filter based on my FR4 stock (bought cheaply from Poland), I doubt anyone can use the masures right off and procude a filter on the exact frequency of 1013MHz.

It's all right to make the design and then immediately produce a batch with that material. Fine if you are in the filter manufacturing business.

I broke my last 1mm fine end mill a week ago so I'll first try to design a filter with the minimum measureof 1.5mm somewhere. If that is not possible, I'll order some new mill bit on Monday.

I have some windows of opportunity for garage work this weekend and the upcoming week for this.

With some luck, I can design a "good enough" filter design, who knows...

Scotty,

What data would your "ideal" filter have?

You might want to consider that FR4 is an unstable substrate. Its parameters vary with temperature, moisture content and temperature. They vary widely from batch to batch. You might want to consider backing the substrate prior to any usage and sealing it after you are finished. I have no idea of how critical the above is to your design, but I think they are worth considering.

Jurgen,

The filter needs a box with 10mm space above the surface and 10mm around. I will probably make a "proper" milled box if theis works out. That should keep the moisture within workabe ranges and in worst case, I can make an oven out of it with rather simple means.

However,

If it works out nicely, I do have a batch of Rogers around in the shack. I just don't want to "waste" it while testing stuff.

I have a decent VNA so I will be able to abuse the design a bit...

Dan,

My suggestion would be to bake the material prior to usage.
I used to work in Telecom and Automotive. We considered FR4 as a sponge.
When we used Fr4 in controlled impedance applications after receiving
the substrate we baked it under vacuum for 72 Hrs @ ~115 degrees C.
I realize that this is not possible but shows the importance.
I also worked on a project in Automotive attemting to replace ceramic
substrates with FR4 and run into the same issues.
My suggestion would be to bake the substrate, make sure not exceed the
temperature do your milling etc. and then seal the substrate with
conformal coating.
This may have the undesirable side effect of changing the filter
characteristics, I don't know.

Jurgen

From: Dan Andersson
Topic: 8375 Message: 8416

Well Jurgen

I'm not going to build a satellite nor any nuclear device :)

The test is to see if I can achieve the bandwidth of a cavity filter, with as many of the cavity filters benefits as possible - but with a PCB.
I'm targeting a "good enough" design here.

I have a design ready now for an initial prototype and I'm going to th garage to start up the cnc mill in a bit.

If I can achieve the basic attenuation and bandwidth independently on where the Fo ends up, it's enough to allow for measurements.

Another question as you brought it up. What is the humidity and temp behaviour of the "cheapo" (bad wording, I know...) built cavity filters in use now?

If the PCB design shows a reasonable fit in that deviation curve, it's good enough.

The nitty gritty of any deviations is the centre frequency and insertion loss. If these two values (the first s most important) is stable enough to use, so be it.

Also, bear in mind that you need to calibrate your SA after it settled in the lab/shack. That should keep it stable enough during the works and measuring - as long as the XYL doesn't open the window (eek! Fresh air!) or you run silly with the linear and creates a sauna environment.

And if you need to recalibrate the SA every day or even twice a day, so be it...

This means I need to mill the PCB at "normal" temp and humidity... :) Imagine, a filter that works only on the UK East coast...

Actually Digikey's international shipment cost to the UK is quite reasonable. It is £12 (about $19) for orders less than £50 and FREE for orders greater than £50. Unfortunately, in the UK we have to pay VAT on everything which adds another 20%.
I have never tried Mouser so I can't comment on their costs.

The latest beta, which is beta version "F" but is titled MSA_version116-4L and is posted in the Files section, handles all configurations, except that we have an unreleased bug fix relating to the use of 4112-type PLLs when using USB to directly control the modules (i.e. no control board). We don't have separate versions of the software for different hardware configurations. I think we will soon be able to release the final software, which will revert to the name "spectrumanalyzer.bas" rather than the form MSA_version116-xx.

Yahoo group: spectrumanalyzer (2011)
Date: 2011-08-20 22:28:47 UTC
From: william sprowls
Topic: 8375 Message: 8420

Hi Dan and All,
No doubt, a microwave filter using FR4 is expected to change characteristics due to many factors. But let's evaluate the main goal of the 1st IF filter. It is maximum attenuation at the image frequency of 1034.7 MHz. We can rate that attenuation with my "taste scale":
worse than -70 dBc = sucks
-70 dBc to -80 dBc = edible
-80 dBc to -90 dBc = tasty
-90 dBc to -100 dBc = darn good
-100 dBc or better = "slap yo mamma" delicious (Jim, in Denver made one for the Verification MSA, and it measures -112 dBc)
Now, these vaues are only important during Spectrum Analyzer operation, not during VNA operation. For VNA operation, you may substitute the cavity filter with a wide band dog turd.
The bandwidth of the 1st IF filter (cavity filter) needs to be at least as wide as the widest Resolution Filter. Normally, the narrower the bandwidth of the cavity filter, the better the image frequency attenuation will be.

The present 4 banger, coaxial cavity filter does not change insertion loss, bandwidth, or its image attenuation with temperature or humidity. It does with vibration, but this is typical for mechanical filters. It does change its center frequency with temperature, and that is noticeable only during VNA operation. It shows up as a phase drift, about 1 degree of phase for every 1 degree of temperature change (F). However, due to other devices in the MSA/VNA the total phase variation in the Verification VNA is .42 degrees of phase for every 1 degree of temperature change (F). (The other devices move in the oposite direction). This is no big deal, since line calibrations compensate for MSA phase changes. Line calibrations are usually performed within 5 minutes of a test, and (usually) temperature changes very little in 5 minutes. There are several VNA users who go nuts when phase changes a few tenths of a degree (you know who you are). I don't get too
upset over a 1 or 2 degree phase change. Most of my home projects are not that critical for Phase.

Hiya Scotty,

Yes, I know what you mean :)

I do have access to some absurdly priced magic software and I get decent

results from it almost every time. And yes, some iterations is required every

time I do a filter design as the dielectrical constant varies from supplier to supplier and even batch to batch.

I don't even try to do cavity filters, even with the software help. I remember they used to burn these kindof engineers on a stake in Halem as witches and magicians once upon a time)

But the main problem is that if I design (with fiftyleven iterations) a working filter based on my FR4 stock (bought cheaply from Poland), I doubt anyone can use the masures right off and procude a filter on the exact frequency of 1013MHz.

It's all right to make the design and then immediately produce a batch with that material. Fine if you are in the filter manufacturing business.

I broke my last 1mm fine end mill a week ago so I'll first try to design a filter with the minimum measureof 1.5mm somewhere. If that is not possible, I'll order some new mill bit on Monday.

I have some windows of opportunity for garage work this weekend and the upcoming week for this.

With some luck, I can design a "good enough" filter design, who knows...

Scotty,

What data would your "ideal" filter have?

Hi All,
 A few comments:
 Below Sam's post is one from Jim W1JGH. He stated:
a) THE MUN2211 buffers must be changed to 2N7002 FETs. Each one must have a 10K pull down resistor from gate to ground and a 4K7 pull up resistor. A 100pF cap MAY be needed from gate to ground.
  This is not an absolute "must", since the present (and future) software will compensate for the MUN2211's poor performance. However, I will make this change in the next revision of the SLIM-ADC module. You may modify your SLIM-ADC-12 or SLIM-ADC-16 if you wish. The 2N7002 fits perfectly on the pwb pads of the removed MUN2211.

Jim Hontoria and I have been evaluating the USB with our MSAs. We are each using a Cypress FX2 board that he purchased on E-bay. He is using USB to control the modules directly. I am using USB to control the SLIM Control Board. Both configurations are working better than I had expected. Dave has written Cypress firmware to take advantage of its embedded processing capability. This has resulted in a very speedy system. Quite comparable to using only the parallel LPT port.
 We are using software version116-4P, which is a "pre-Beta" version. This was to clear up a few problems with "talking" to the USB. It is basically the same as version116-4L.
  A full release of Version 116 is soon to happen, but we need to do a few more "fine tunes" of the USB area first. To those of you who only have USB on your computer this is really good news.

Well,

The first two filters came out rather bad... Both on 934MHz centre which is a good thing as they have almost identical curves.

The filters are both Interdigital fillters with cct input
but they doesn't like 1.5mm FR4. I thnk I remember the 1.5mm as a problem I ran inte years ago but I don't remember what and why.

I'll mill the same recipe on 0.8mm FR4 tomorrow.

All recent versions (since September 2010) of the software are common to USB and Control Board. The hardware selections (USB, CB, 4112 and others) are made through setup.

Hi Dan,
 Let me make a suggestion. Create a Folder in our Photos section of the Yahoo Group. Take pics or plots of all of your trials and errors. Failures are always on the road to success. Someone might see a "trend" in your experiments and could offer some advice. I, for one, would like to see your results.
Scotty

Well,

The first two filters came out rather bad... Both on 934MHz centre which is a

good thing as they have almost identical curves.

The filters are both Interdigital fillters with cct input

but they doesn't like 1.5mm FR4. I thnk I remember the 1.5mm as a problem I

ran inte years ago but I don't remember what and why.

I'll mill the same recipe on 0.8mm FR4 tomorrow.

I found out why 1.5mm is a bad idea.

Years ago, when I built the S53MV's SA design, he points out that to thick FR4 allows for to strong coupling between the microstrip resonators and subsequently not working as a filter. To much signal is coubled independently of the microstrip sizes.

So - 0.8mm it is.

-- Which introduces another problem, size.

The space between the microstrips are down to 0.6mm and I don'tr have any 0.5mm mill bits on the shelf.

I will look for workarounds but have to order some in worst case.
0.5mm mill bit will probably be very shortlived and I'm not to keen on it.

I usually takes snaps with my iPhone on the stuff I make. I'll see what's suitable to upload to the group.

Again, I don't search for perfection, just a "good enough" design to be useful based on Scotty's "whishes".

Cheers

Dan

in genreal I do not believe that it will be possible to build a stripline filter on FR4 or even Rogers material having such a steep filter curve and low insertion loss!
The reason: the limited unloade quality factor of the material, ecthing tolerances etc.

Betreff: Re: [spectrumanalyzer] Re: BW of filters

Wide band dog turd,
How convenient, I have lots of those.

Hi Dan and All,
No doubt, a microwave filter using FR4 is expected to change characteristics due to many factors. But let's evaluate the main goal of the 1st IF filter. It is maximum attenuation at the image frequency of 1034.7 MHz. We can rate that attenuation with my "taste scale":
worse than -70 dBc = sucks
-70 dBc to -80 dBc = edible
-80 dBc to -90 dBc = tasty
-90 dBc to -100 dBc = darn good
-100 dBc or better = "slap yo mamma" delicious (Jim, in Denver made one for the Verification MSA, and it measures -112 dBc)
Now, these vaues are only important during Spectrum Analyzer operation, not during VNA operation. For VNA operation, you may substitute the cavity filter with a wide band dog turd.
The bandwidth of the 1st IF filter (cavity filter) needs to be at least as wide as the widest Resolution Filter. Normally, the narrower the bandwidth of the cavity filter, the better the image frequency attenuation will be.

The present 4 banger, coaxial cavity filter does not change insertion loss, bandwidth, or its image attenuation with temperature or humidity. It does with vibration, but this is typical for mechanical filters. It does change its center frequency with temperature, and that is noticeable only during VNA operation. It shows up as a phase drift, about 1 degree of phase for every 1 degree of temperature change (F). However, due to other devices in the MSA/VNA the total phase variation in the Verification VNA is .42 degrees of phase for every 1 degree of temperature change (F). (The other devices move in the oposite direction). This is no big deal, since line calibrations compensate for MSA phase changes. Line calibrations are usually performed within 5 minutes of a test, and (usually) temperature changes very little in 5 minutes. There are several VNA users who go nuts when phase changes a few tenths of a degree (you know who you are). I don't get too upset over a 1 or 2 degree phase

change. Most of my home projects are not that critical for Phase.

Hiya Scotty,

Yes, I know what you mean :)

I do have access to some absurdly priced magic software and I get decent results from it almost every time. And yes, some iterations is required every time I do a filter design as the dielectrical constant varies from supplier to supplier and even batch to batch.

I don't even try to do cavity filters, even with the software help. I remember they used to burn these kindof engineers on a stake in Halem as witches and magicians once upon a time)

But the main problem is that if I design (with fiftyleven iterations) a working filter based on my FR4 stock (bought cheaply from Poland), I doubt anyone can use the masures right off and procude a filter on the exact frequency of 1013MHz.

It's all right to make the design and then immediately produce a batch with that material. Fine if you are in the filter manufacturing business.

I broke my last 1mm fine end mill a week ago so I'll first try to design a filter with the minimum measureof 1.5mm somewhere. If that is not possible, I'll order some new mill bit on Monday.

I have some windows of opportunity for garage work this weekend and the upcoming week for this.

With some luck, I can design a "good enough" filter design, who knows...

Scotty,

What data would your "ideal" filter have?

Henning,

The quality factor of the material is not the show stopper.
Nor is the etching tolerances.

I can make stuff down to better than 0.0002" (averaging on 0.0001"), about 5 micron and averaging on 2.5 micron.

This is my "repeatability", not maximum accuracy. I can't measure below 1 micron at home :)

As rocket science is one of the simplest and developed and a well defined sciences (except if you work at NASA'a nightshift and mix imperials with metrics :) so this should not be suffering a total block.
But as microwave filter design is like rocket science, the building is not...

I'm rather certain we can build ONE working filter - but maybe not two or three.

As you point out, the tolerances are small with the narrow bandwidth required for the filter.

Even if I can produce a couple of good enough filters, I doubt anyone else can take the desig data and produce a working copy without going through the tuning iterations again. Also, I bought my FR4 from a Polish supplier. Who knows who produced it and I don't know the dielectrical constand. I required, I can of course measure it but...

The cavity filter and it's derivatives are without discussion the best solution. However, good ones are difficult to come by and diy is a bit twitch with a good amount of magic required.

I'm only trying to find out if I can make a "good enough" PCB based microstrip filter.

There was an excellent article on computer aided interdigital bandpass filter design in the January 1985 issue of Ham Radio. You can read it online at www.qsl.net/n9zia/spec/idbpf.pdf

The program has been ported to a web server at http://www.wa4dsy.net/cgi-bin/idbpf

A useful explanation and the original Basic code can be found at http://www.wa4dsy.net/idbpfdraw.html

I used the program to build two filters for the 1296 MHz ham band using a milling machine. Both filters tuned up perfectly on a spectrum analyzer in a few minutes and worked perfectly the first time. If you don't have a milling machine you should be able to build one by soldering copper clad pc material to the same dimensions. There was no black art or witchcraft involved.

Not for nothing, but I had always been very intimidated by the cavity filters. Because I'm still dealing with digital signaling nastiness (the reason for building a USB control board), I hadn't been able to test my filters. I borrowed a cheepie spectrum analyzer with tracking generator from work (and believe me, it's not very good), and found that they both work! I was able to tune them to 1013.4 Mhz with 2 Mhz BW (-3dB points). I think that I have at least 86dB of isolation.

I'm not totally confident in my measurement techniques, especially considering this analyzer doesn't have any measurement tools built-in. It only has a center frequency display and a marker. It also has a poor noise floor.

Measure the insertion loss:

The top line measurement from the tracking generator is at +1dBm with 20dB is attenuation on the input -> -19dBm w/o the filter installed. With the filter installed it drops down 6dB from the top line. Therefore the insertion loss is 6dB.

Measure the isolation

Starting with the same settings as before (-19dBm out of the TG) and the peak of the filter center at 6dB below the top, the noise floor is 66dB down from the peak. I can turn off 20dB of attenuation and the noise floor doesn't move. I think this means that I have _at least_ 86dB of isolation.

The bandwidth measurement seems trivial.

Anyway, I'm happy that building the cavity filter wasn't NEARLY as hard as I thought it would be. And, I'm pleased that I have a filter that is (at least) somewhere between "tasty" and "edible"!

So,

Got my new mill bit.

I will now be able to mill with 0.1mm cut and +/- 0.001" repeatability.

(Sorry for the mixed units...)

I wonder how long before I break that 0.1mm mill bit!

Anyone else with ideas and drawing of a PCB based filter.

I can take Gerber, Gcode and possibly DXF and some bitmaps as well.

Double left click anywhere in the vinicity of the Y axis you want to change to bring up a window where you can select the top and bottom reference, number of divisions and a few other parameters. Can't remember where I found the info, it was a long time ago.

Just right click on the right edge of the display (probably you have it at 0-100 dBm). It will open a window where you can set the magnitude scale to your hearts content.

Jim,
I was working on one, but got diverted. I think the best approach is to use an HF3-06 relay (12V, non-latching) (Mouser) and drive it via a buffer (maybe just a transistor) from the Band control bit. (Be sure to put a protection diode across the coil.) This relay operates fine off 10V and draws only about 10 ma so there is no need to mess with latching circuitry. Its isolation at 10 MHz is on the order of 100 dB.

If the diplexer contains attenuation in the 10.7 MHz (2G) output that approximately equals the losses that would occur in the cavity filter and Mixer 2, 100 dB of isolation in the band switch should be plenty.

I also have a board that I designed as a transmission/reflection switch, using 3 PE421's, which design could also be used for the band switch, though its isolation would be complete overkill at 10.7 MHz. It's been sitting next to my MSA for 2 months waiting for me to build it.

Date: 2011-08-26 19:08:27 UTC
From: Eric Nystrom
Topic: 8442 Message: 8442

I am on step 13 in the DDS testing where the procedure calls for sweeping the DDS output filter. I have set everything according to the procedure, but the frequency of the DDS stays fixed at 10.7 MHz. I am using the download from the files section entitled version 116_4L. I have run both the .exe version and the .bas version. I have the

variables displayed and I can see the DDS1 output frequency sweeping in the variables. I have attached a logic analyzer to the three control lines for the DDS and they are updated
periodically, but the serial data stream does not change.

Am I missing something obvious?

Hi Eric,
 First, I have verified this test is still working fine with the Verification MSA using the software version 116-4L.
 This is testing DDS 1 so make sure you don't get DDS 3 confused. You should be getting a screen response that looks like a pulse. Its width depends on the response of the DDS 1 crystal filter. Using the specified filter, it should be about 20 KHz wide.
 What is your indication that the frequency output of DDS 1 is not changing and stays at 10.7 KHz?
  Go ahead and do step 14. This verifies that the DDS1 is commanding properly, and outputting the correct frequency. In this case it is 1 cycle every 10 seconds.

Putting the switch on the diplexer board, as you have done, is a good idea. The ADG918 might be worth a try. I can't figure out its data sheet. it shows S21 off-isolation in the low 80's but S12 off-isolation in the 60's. I can't see how they can be significantly different. 80's might work, but 60's is weak.

You could use exactly the same approach with the PE4251. It would give you 85 dB of isolation. At that level, the major vulnerability would be having a strong 10.7 MHz signal in the input, that could leak directly through Mixer 1 and the switch when in 1G mode, and would show up at all frequencies like an increase in the noise floor. That's purely an SA issue, and probably not a big problem.

You also have a direct Vdd connection, for which you probably need to reduce the voltage. A voltage divider with a bypass cap would work.

The problem I see with the Peregrine switch is that below 10 MHz the linearity is poor and I don't know if the calibration will take care of that. It is specified from 10MHz up, so the very low frequencies are toast.

I am also looking at the MiniCircuits HSA2-30DR that has very nice curves but the isolation may be too low.

I have prepared layouts for all threee alternatives, including pads for a voltage divider and decoupling cap.

PE4251 looks ok, I have been using it for this purpose for while, and I did not see any problem.

I did some investigation into the issue of non-linearity below 10 MHz. It is only relevant at fairly high powers, as it has to do with an internal diode becoming conductive at higher powers. Below 0 dBm it is a complete non-issue. It kicks in above that at some level that depends on frequency.

8448. The 0.1% resistors for shunt and serial fixture

Yahoo group: spectrumanalyzer (2011)
Date: 2011-08-29 16:38:50 UTC
From: inlinebeginner
Topic: 8448 Message: 8448

Sam
The 0.1% 62 ohm resisotr in the shunt fixture circuit (VNA guide) might be 61.9 ohm 0.1%, is that right?
I could not find the 127ohm 0.1% for the serial fixture, Digikey is 0 QTY available. Where did you buy this resistor?
Did anyone publish a verification data for the RLC model measurement? I tested a 100pF cap, with fiture made of 1% resistor, and got the following result:
Fs=263.2375 MHz; R=15.34 ohms; L=4.349 nH; C=84.04 pF; Qu=0.469; QL=0.288
I measured same cap with Smith chart on HP8753E, I got 100.1pF, differenct from 84.04pF.
Maybe the 1% resistor is not good enough?
Thanks
Lin

Lin,
Mouser is generally a better source for precision resistors, and has the 62 and 127 ohm 0.1% resistors. But 61.9 should work fine in place of 62.

I did a lot of testing with RLC analysis and it performed very well. However, RLC analysis in Transmission mode, which I suspect you were using, uses just simple Thru calibration and is not as accurate as RLC in Reflection mode in these circumstances:

1. Higher frequencies. With such simple calibration, the shunt fixture loses accuracy above 100 MHz, and even below that it may be necessary to specify the "delay", which is the one-way time delay from the point where the fixture attenuators connect to the end of the connector to which the DUT connects. You can make a decent estimate of that time delay based on the connector length. If you are measuring components on the back of an SMA connector that is attached to the SMA connector of the fixture, the delay should include both connectors.

2. If your TG output or MSA input are far from 50 ohms, the internal attenuation of the shunt fixture may not be high enough for extreme accuracy, and you need to add attenuation either externally or by building a shunt fixture with higher internal attenuation.

In reflection mode, OSL calibration corrects for all these errors, and also corrects for errors in the fixture resistors. Transmission mode RLC is really intended for relatively low frequency use where the above issues are normally minor. Your measurements are made near 263 MHz, where it is probably necessary to use Reflection mode. I'm guessing you used Transmission mode.

Sam
Thanks for the information. For the 127 ohm 0.1%, looks like I have to wait for the lead time, even order from mouser.com. I found a 0.05% LCR bridge and screened some 1% resistor with this bridge. The two resistor I screened should be a little bit better than 0.1%.
Yes, I tried to meausre some cap, 1p, 10p, 100p to put into the simulation, the transmission mode may not reach that high frequency.
I tried reflection mode with a 1GHz DC, the phase jump from -180 to 180 degree is very noisy, SRF around 590MHz. The temperature drift made might be a problem during the test. I can try more later and publish the screenshot.

Hi,

I am early on in the project. I just received my panel of boards and I am beginning construction of the Control Board. I plan on constructing my enclosure using Brass panels. What thickness/gauge is preferable? Also what size angle brackets for re-enforcement?
Thanks
Vince

Hi Vince,
Good question. I used double sided .062 FR4 as panel enclosure. Very sturdy and easy to solder to.
 If you want to use brass, I would suggest anything between .031 (1/32) and .062 (1/16). Thick is fine, but difficult to solder. For either, you don't need much bracing. Your angle brackets will perform as bracing (3/4 inch triangles). Use one on each corner, on the top and on the bottom (8). They provide a place to screw down covers (top and bottom), and rubber feet (bottom). My bottom cover is held in place only when the threaded (6-32) rubber feet are installed. Your style of "egg carton" to hold the modules will also perform as bracing.
Scotty

I used 0.032" brass for the sides. Each was a 4"x10" panel because I could buy that size and didn't have to do any cutting, though I think 5" x 12" would be ideal. I used brass angle much as Scotty describes, except I did not put angle around the top of the sides, but rather put it on the sides of the top cover (top and bottom covers were made of 0.062" FR4), so it wouldn't be in the way when I took the cover off. I also ended up putting a reinforcing bar of tiny brass angle from front to back at center top, and ended up hanging my support grid from it.

For brass angle, you have a choice of relatively thin material with wide sides, or thicker material with narrower sides; I went with the latter.

At Home Depot I found clamps designed to hold wood or sheet metal at right angles, and it worked great. I could clamp two sides together, and there was room to slide the brass angle on the corner and solder it. It was the first box I ever made that was actually square.

Hi Vince,

For what it's worth, I thought I would point out that I made my MSA enclosure out of a combination of wood and brass. No soldering. See

http://groups.yahoo.com/group/spectrumanalyzer/photos/album/995283679/pic/159422940/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc

If the integrity of the individual module sealing is maintained, I don't believe that it is necessary to have a totally enclosed metal box. The noise/spur levels I obtained appear very consistent with what others have gotten.

Good luck with your project.

Neal

Neal,
It looks great. Is that Plywood? The only drawback is my woodworking skills are not too great. I do have a 9" bandsaw that I am using to cut out the circuit boards from the panel. What kind of wood working tools did you use for your cabinet?

8457. Relay for Transmisson Reflection Bridge

Yahoo group: spectrumanalyzer (2011)

From: Eric Nystrom
Topic: 8451 Message: 8457

I am looking for parts for the Transmission Reflection Bridge and a HF3 56 Relay is specified. They don't appear to be available anywhere that I can find.

Would the HF3 06 which is a 75 ohm relay work? I noticed that one was mentioned in a recent discussion for use with the band switching hardware.

Sam,
I was thinking about the "making it square" problem too and how I would hold the plates together while soldering. Do you have a Home Depot skew number for those clamps or a jpeg even? Sometimes asking the store help doesn't always produce what you are looking for. If not I will try to describe it to them as best as I can and see what they produce.
Also this site claims they will do custom cuts. I think I will go with .032".
<http://www.onlinemetals.com/merchant.cfm?pid=1591&step=4&showunits=inches&id=1116&top_cat=79>

Thanks much
Vince

Making it square?

The simplest way is to make a square bit of wood as a template. If you have 3 different size of enclosures to make - then make three wooden templates.

I built a couple of S53MV spectrum analyzers this way. The boxes looks like being fabricated in a factory.

I'm cheating by having nicely cut sheets to start with but even a thin copper/brass sheet metal is stiff enouigh to be used a an enclosure.

Unless you plan using the enclosure for controlled crash experiments.

Ideally, one can of course mill enclosures out of solid aluminium or brass blocks but a 1" by 1" and 3/4" deeps alu enclosure takes almost a quarter of a day to mill if you require smooth surfaces and small cvuts to prevent heating and broken bits.

Also, by using milled alu or brass boxes, a temperature stabilizing factor is introduced. It takes time for these enclosures to change temperature if the outer temp is changing. Especially if the enclosures are mounted on a temp controlled base plate. It's simple to make an "oven" with a couple of lamps and a temp control.

Overkill? Yes of course :) but it shuts up the owners of professional (expensive) SA's.

If you are talking about my Transmission/Reflection bridge that combines the Active Bridge and buffer amp with a relay, you need a non-latching relay. For some reason, nobody seems to carry the 50-ohm versions any more, but Mouser has the 75-ohm HF3-06 that will work fine. It's nominally 12V, but the specs allow as low as 9V.

A note on the design in case anyone is designing their own: The bridge DUT port drives the DUT, whose output is buffered by the buffer amp and then runs to the Transmission leg of the relay. The reflection output from the bridge runs to the Reflection leg of the relay. It is very important that the DUT output sees the same load no matter what the relay setting, and ideally that load is 50 ohms. If it weren't for the buffer amp, the DUT would see high impedance when Reflection is selected, and the impedance of the MSA input when Transmission is selected. With the buffer amp, the DUT output is completely isolated from the relay setting. The bridge output is also isolated from the relay due to an op amp and attenuator. The attenuator's main purpose is actually to reduce the max reflection output, to avoid a strong reflection interfering with a weak transmission due to leakage in the relay.

The isolation from the relay is one reason that a 75-ohm relay is acceptable.

They are stamped Pony No. 9166, which is the only ID. You'll find them at Amazon if you search for Pony 9166. Buying them directly from Amazon is expensive, but there are some cheap alternatives through Amazon associates.

Eric,
I just went on Digikey and the HF306 is their number PB1105CT-ND. They seem to have enough of them at about $4.50.

8466. Measuring output impedance?

Yahoo group: spectrumanalyzer (2011)
Date: 2011-09-13 21:01:32 UTC
From: William Dillon
Topic: 8466 Message: 8466

Hi everyone,

Sorry if this verges on being off-topic, but I figure that there is likely to be some relevant expertise here. I would like to measure the output impedance of a device. I don't have access to the schematics of said device, so let's consider it a "black box". It's certainly possible to measure the output spectrum using the SA, but is it possible to accurately measure the output power without knowing the output impedance? The device in question has a soldered-in wire whip antenna. I was hoping to install a SMA connector to it, but I don't know if the design assumes some other impedance than 50 ohms.

Thanks in advance!
- Will
KD7VMY

From: Sam
Topic: 8466 Message: 8467

It is true that the SA measures the output power of the device into a 50 ohm load. If the load is not 50 ohms, the actual output power will depend not only on the actual load impedance, but on the device output impedance.

As I understand your device, the "load" is the antenna. If you can remove the antenna and attach an SMA to the remaining device, and another SMA to the antenna, you can measure both the output impedance of the device-sans-antenna and the input impedance of the antenna, as well as the power output from the device-sans-antenna. There is some distortion because when the antenna is attached to the main device no SMA connectors were involved, but this will be a minimal issue if you are operating at relatively low frequency.

I don't have at hand the formula that would convert the SA measured power to power-into-actual-load, but I think it would be straightforward.

Measuring an output impedance is done just like measuring an input impedance, except that for power amps the output impedance may depend on output level, so you need to have the amp producing a signal to get an accurate measurement. This means it may not be feasible to hook the amp output directly to a bridge, because the amp output signal will get driven into the TG terminal. If you face that situation, see <http://groups.yahoo.com/group/VNWA/files/SWetterlin/MeasuringHotZout.pdf>

Will,

If you work on relatively low frequencies, try the simple way.

Connect a 0-1000 Ohm pot to a SMA. (or whatever coves your impedance to be measured)

Connect your impedance sotce > Power Meter > SMA with pot

Adjust pot for max power. Measure the resistance of the pot.

The higher the frequency, the more inaccuracies but below 100Mhz or so, it's very accurate.

Thanks Sam and Dan!

That's pretty good info

I'm pending membership in the VNWA group, so I'll look at the document when I can.

For now, because I don't have a pass-through power meter that goes low enough for this device I think I may be able to use a directional coupler that I have with a spectrum analyzer. I like the simple idea of using the pot, I'll try that out.

```
* SA
|____|
DUT >------> POT
```

* = 50 ohm load

Also, I'm assuming that the directions are correct on the DC. I could always reverse them and measure fwd and reflected power as a final check.

Excuse the ASCII art :)

Will,

Normally, we don't care abt the output impedance. Depending on the TX device, the output impedance is very un-linear. Depends on frequency and power.

To plot the output impedance, you need a 3D (XYZ) plot with Frequency, Power, Impedance in the XYZ order.

You need to have a good reason to bother with it.

In this case I'm trying to make sure that the output of the "black box" transmitter is close enough to the input of a power amplifier. The frequency and power are fixed.

8472. Cavity Filter Questions

Yahoo group: spectrumanalyzer (2011)
Date: 2011-09-14 12:38:57 UTC
From: Eric Nystrom
Topic: 8472 Message: 8472

I am ready to build my cavity filter and have some questions.

Will there be any significant difference in using copper vs brass for the center stub?

If copper pipe is used, should the end be plugged?

Any hints on the best way to strip the shield from RG402?

Thanks

Eric Nystrom

Hi Will,
Just for the sake of argument, you are wanting to match the output of a 440 MHz Handi-talki to an amplifier.
Alas, you are right, the antenna will not likely represent 50 ohms. Internal to the HT is a matching circuit between the final transistor and the rubber ducky antenna. Just replacing the antenna with a 50 ohm type SMA connector is a good start. You must then construct a matching circuit that converts the impedance of the missing antenna to 50 ohms. And, it must be extremely close to the removed antenna connection.
It it were me, I would build the matching circuit internally, between the antenna tie point and the new sma connector. Since this is fairly low power (under 5 watts), components will be small.

My suggestion would be to remove the antenna, and mount it in a similar arrangement on a sma connector. Then use the VNA to find the impedance of the antenna. The value would then be a good starting value for your new impedance matching circuit.

Hi Eric,
Yes, but I couldn't predict it. I have never tried brass.
The center stub needs to be open at the top to allow the tuning screw to enter it (if necessary). The bottom may or may not be plugged. Makes no electrical difference. Wasps could enter a build a nest.
Scribe the circumference of the hard pipe with an Exacto knife and bend back and forth a couple of times. It will "snap".

I have used brass for the bodies (not the rods) of cavity filters. It increases the insertion loss (I don't recall the amount) due to its higher resistivity. The large surface area of the cavity wall somewhat reduces the importance of resistivity, but with the far smaller surface area of the rod I would expect brass to at least double the insertion loss. Silver plating the rod would solve the problem; it wouldn't be necessary to plate the entire cavity.

8476. PLO 1 Debugging

Yahoo group: spectrumanalyzer (2011)
Date: 2011-09-14 22:20:06 UTC
From: Eric Nystrom
Topic: 8476 Message: 8476

I am building the VNA version and have built two of the PLO 1 modules. One works and the other fails to lock.

On the one that fails, all the voltage and current readings are good except for the loop balance
voltage and the VCO control voltage. I measured the VCO control voltage and noticed that when I power it up and start the software, the voltage slowly drifts up to around 19 volts. If I
use the volt meter to check the 4118 output on pin 2, the VCO control voltage goes to 19 volts
right away.
Any suggestions of further tests?

Thanks.

Eric Nystrom

8477. Re: [spectrumanalyzer] PLO 1 Debugging

Topic: 8476 Message: 8477

Hi Eric,
  This would indicate that the PLL pin 2 is "floating", in a Hi-Z mode. The op amp circuit sounds like it is working. I believe that the PLL chip will power up in a mode called "standby" and will stay there until it receives the proper command (from the control board). The "standby" mode will cause pin 2 to float.
  Make sure your comparisons of the two PLO's are "apples to apples". That is, if PLO 1 is working fine in its position as PLO1, then remove it and replace it with the non-functional PLO in that position. This guarantees the same input signals to the modules. If still non-functional, you can eliminate possible external failures, such as a bad clock from the DDS or a bad command from the Control Board.
  Of course, I always suggest a triple inspection of solder joints on the PLL chip (especially pin 2).

Scotty,

Thanks for the suggestions. The control wiring is attached with connectors so everything is
common between the tests except the boards. I checked all the soldering again and touched it up to make sure. I also checked the three control lines with an oscilloscope and the signals
are getting to the pins at the chip.

Have you ever tried programming the functions on the MUXOUT pin for this chip? It would be a way to verify the chip is working by viewing the outputs of the R and N counters.

I will order another 4118 and replace it and see what happens.

Eric Nystrom

Did you buy the PLL on ebay, by chance? I had similar issues. Guess it was a lemon.

Hi,

If you want to experiment with the communication and settings of the pll chip I'd suggest you visit the site of analog devices. You can download a nice free tool to try out various pll chips. It works with an easy diy interface cable on the parallel port.

I am building the VNA version and have built two of the PLO 1 modules. One works
and the other fails to lock.

On the one that fails, all the voltage and current readings are good except for the loop
balance
voltage and the VCO control voltage. I measured the VCO control voltage and noticed that
when I power it up and start the software, the voltage slowly drifts up to around 19 volts.
If I
use the volt meter to check the 4118 output on pin 2, the VCO control voltage goes to 19
volts
right away.

Any suggestions of further tests?

Thanks.

Eric Nystrom

Hi Eric,
 I have with the LMX2326 but I don't have the 4118 to verify. Should be the same. Here is how to program the PLL chip to allow pin 14 to show results:
In the spectrumanalyzer.bas code find [Command2326R].
Bits N4-N6 control pin 14:
default Code for LMX2326

```
    N6=0        'FoLD control(pin14 output), 0= tristate, 1= R Divider out
    N5=0        '2= N Divider out, 3= Serial Data Output, 4= Digital Lock Detect
    N4=0        '5= Open drain lock detect, 6= High output, 7= Low output
```

The ADF4118 is different, so just change the bits to get the following:

```
    N6=1        4= R Divider out on pin 14

    N5=0

    N4=0

    N6=0

    N5=1        '2= N Divider out on pin 14

    N4=0

    N6=1

    N5=1

    N4=0        6= Serial command, inverted, on pin 14

    N6=0

    N5=1

    N4=1        3= AVdd output on pin 14 (5 volts)

    N6=1

    N5=1

    N4=1        7= Low output on pin 14 (0 volts)
```

These last two prove the PLL chip is getting a proper command and can be measured with a voltmeter.

Scotty,

Thanks for the help. I did the test of setting MUXOUT to output AVdd. On the good board the output was as expected and on the one that was not working, it stayed at 0 volts. I have removed the chip and ordered another one.

From: ed_k7ock
Topic: 8472 Message: 8484

I used 1/4 " solid brass rod for the cavity filter,threaded on one end so I could do the adjustments. Fortunately I had access to the Agilent FieldFox network/spectrum analyzer to do the adjustments.I was able to get it adjusted to the correct center frequency with about 3 MHz bandwidth, if I remember correctly the insertion loss was a little over 8 dB and the image rejection was close to 90 dB.

Now if I can get my act together, I will finalize the construction and start cal.

Ed

--- In spectrumanalyzer@yahoogroups.com, "Sam" <swetterlin@...> wrote:
>
> I have used brass for the bodies (not the rods) of cavity filters. It increases the insertion loss (I don't recall the amount) due to its higher resistivity. The large surface area of the cavity wall somewhat reduces the importance of resistivity, but with the far smaller surface area of the rod I would expect brass to at least double the insertion loss. Silver plating the rod would solve the problem; it wouldn't be necessary to plate the entire cavity.

8485. Band switching software bug

Yahoo group: spectrumanalyzer (2011)
Date: 2011-09-17 14:39:08 UTC
From: jghbeta
Topic: 8485 Message: 8485

Sam, Scotty,

It appears there is a glitch in the 1G-2G selection software.
Tried to switch to 2G and got a message "Sig-Gen was out of band. Changed to 10.0" Then nothing happens and the hour glass stays for ever. The Sig. gen, in any case was 10 MHz to begin with. The good news is that the bits flip , the bad is that the Restart button becomes inoperative.

Jim, W1JGH

8486. Re: [spectrumanalyzer] PLO 1 Debugging

From: Eric Nystrom
Topic: 8476 Message: 8486

I replaced the 4118 on the PLO and it now works. I had low output on J3 so I replace U8. Now the output from J2 and J3 are similar.

I have uploaded some files to the following folder.

http://groups.yahoo.com/group/spectrumanalyzer/files/Eric%20W4EON

I was wondering if the wider area the is at roughly -60db on the photo labeled PLO 1 Power Test is correct or indicates the PLO is not locked correctly.

I have also uploaded a file for the PLO 3 Power Test. Does it look correct?

Thanks

Eric Nystrom

From: Sam
Topic: 8485 Message: 8487

Jim,
I suspect a message was printed on the message line, about a PLL error. When you click Restart, it creates the same error, prints the same message, and stops.

In any case, there is an error as to how the signal generator is set for SA mode when not in 1G. The signal generator shouldn't even care what band you are in; it is a freebie feature that operates on its own, making use of LO3 which would otherwise be unused. I am revising it so it will create the desired frequency (sgout) as follows:

sgout=LO3-LO2 if sgout<LO2
sgout=LO3 if sgout>=LO2 and sgout<2*LO2
sgout=LO3+LO2 if sgout>=2*LO2

These ranges allow LO3 to be set somewhere between LO2 and 2*LO2. Unless your +20 supply is very weak, LO3 should be able to cover this range.

Note that all three of these frequencies are always contained in the TG/SG output. It's just a question of which one we make equal to sgout.

Sam W.

From: Sam
Topic: 8476 Message: 8488

Eric,
I believe that stairstep pattern, which for PLO1 creates the step at -60 dBm, is caused by frequency modulation of the VCO. There seems to be a bit of it for PLO3 also. The modulation is likely caused by ripple on the +20V line. You probably need to replace or double up on the 10 uF filter caps on the +20V line on the PLO boards, and also back at the voltage doubler on the control board. Use ceramic X5R or X7R capacitors, 25V or higher.

Sam W.

Topic: 8476 Message: 8489

Hi Eric,
 One way to determine if the voltage doubler has too much ripple is to "kill" its oscillator. A good way to do this is to moisten your finger and press your finger on the pins of the multiplier I.C. Its internal oscillator is easily stopped this way. When stopped, the doubling action ceases and the +20v line will drop to about +9 volts (with absolutely no ripple). 9v is more than enough for PLO1 or PLO 3 to operate and lock at their lower frequencies (MSA or Sig Gen commanded to less than 200 MHz).
This was a "trick" I found accidentally. It will begin oscillating again once the pwb dries. To the "purist" who wants to blast me for the suggestion, save your breath!

Eric,

I believe that stairstep pattern, which for PLO1 creates the step at -60 dBm, is caused by frequency modulation of the VCO. There seems to be a bit of it for PLO3 also. The modulation is likely caused by ripple on the +20V line. You probably need to replace or double up on the 10 uF filter caps on the +20V line on the PLO boards, and also back at the voltage doubler on the control board. Use ceramic X5R or X7R capacitors, 25V or higher.

Jim,
I believe what happened is you changed to 2G but did not change the frequency range to something within 2G. So PLL 1 was trying to be set to an unreachable frequency.

8493. Setting master oscillator frequency

Yahoo group: spectrumanalyzer (2011)
Date: 2011-09-18 22:31:05 UTC
From: Steve
Topic: 8493 Message: 8493

Scotty,

The Initial Set-Up and Calibrationfor the MSA
<http://www.scottyspectrumanalyzer.com/msasetcal.html> web page
describes two beat frequency methods for establishing the master
oscillator frequency.

As an alternative, can the MO frequency be determined by commanding the
tracking generator to 64MHz and reading its output on a frequency
counter? That reading can then be entered into the Mast Clock field on
the Configuration Manager window?

Thanks.

Hi Steve,
 Good question. But, no, the TG can be significantly off its command frequency (+/- 1.3 Hz). This is due to the fact that the DDS is always "rounded off" to its least significant bit. This is an error of only .014 Hz at 10.7 MHz (the DDS output). However, since the 10.7 gets multiplied up to the PLO operating frequency by a factor of 95 or more, so does the error. (95 x .014 Hz = 1.33 Hz). This doesn't sound like much of an error but it really is.

The direct output of the DDS is the easiest MSA source to beat with WWV, since it's error will never be greater than .014 Hz.

Actually, the Master Clock could be measured by a freq counter, but freq counters have error too.
 WWV has no frequency error. (Doppler enthusiasts, leave me alone).

OK, it seemed too easy :-)

I had already constructed the DDS's and boxed them up before realizing
that I should have made the spare outputs available. Absent spare
outputs, neither of the zero-beat methods are available to me.

What I can do, however, is disconnect one of the MO outputs and measure
it with a frequency counter whose time base is the output of a GPS
receiver.
"Doppler enthusiasts" consider that better than WWV :-)

I have finally got my MSA packaged and was hoping the TG output would
work so I wouldn't have to disassemble the unit . . . sigh.

Two PLO's at two different frequencies. Each requires an independent DDS to "steer" it.

The DDS frequencies are not fixed at 10.7 MHz. They are adjusted by tiny amounts to fine tune the PLO frequencies at each scan point.

Scotty,
Maybe it would be useful to calculate the actual SG output frequency when it is set to 10 MHz and/or 64 MHz, for anyone who wants to use a (reliable) frequency counter to determine the MO frequency. Maybe this depends on the PLL used, but there are only 2 or 3 types actually in use.

8501. Re: [spectrumanalyzer] Setting master oscillator frequency

Yahoo group: spectrumanalyzer (2011)
Date: 2011-09-19 14:22:18 UTC
From: william sprowls
Topic: 8493 Message: 8501

Hi All,
Perhaps I may have been a bit blunt in my answer (below). If you measure the frequency of the TG output with a frequency counter, your data will contain two errors:
The "round-off" bit error of the DDS 3 and the error of the frequency counter used. As I stated, the DDS error will be small, less than +/- 2 Hz.
  Also, the error of the freq counter is composed of two errors. The error of its reference and the "least significant bit" error in its counting process. For a freq counter that uses GPS as a source (assume 0 error), the only error is its LSB error. If the counter's resolution is 1 Hz, then 1 Hz will be its LSB error. But, how many of us have GPS "steered" frequency counters? This is why I developed the calibration procedure using WWV.
  The bottom line is, the accuracy of the Master Oscillator Calibration is dependent on the Reference source (WWV or Freq Counter).
  That being said, it is not often that a Spectrum Analyzer is required to have significant frequency accuracy. However, the MSA isn't just an SA. One Function of the MSA really does require frequency accuracy, the Crystal Test Function.
  Even though you may have not connectorized the "spare" port on the DDS 1, its signal is still there on the pad (hole) at J3.
  Once the Master Oscillator is calibrated, we must contend with frequency error due to temperature drift. Although this error is small I am planning an addition to the MSA hardware and software to allow temperature monitoring of the Master Oscillator module. Once calibrated for temp changes, this function will constantly update the actual frequency of the Master Oscillator while the program is running.

Scotty,

The Initial Set-Up and Calibrationfor the MSA

<http://www.scottyspectrumanalyzer.com/msasetcal.html> web page

describes two beat frequency methods for establishing the master

oscillator frequency.

As an alternative, can the MO frequency be determined by commanding the

tracking generator to 64MHz and reading its output on a frequency

counter? That reading can then be entered into the Mast Clock field on

the Configuration Manager window?

Thanks.

From: Eric Nystrom
Topic: 8476 Message: 8507

I added a second 10 uf cap at C20, C21, C24, and C25 on the Control board
and an additional 10 uf at C46 on PLO1 and PLO3.

I found that shielding was necessary to clean up the output of PLO3

The screen shots after the fix can be found at

Eric,
Looks good. When you say you had to shield PLO3, was that just the normal shield around the board (with cover), or did you do extra shielding?

Sam,

It was the normal shielding. I had the MSA sitting on the bench and I found just picking it up from the bench was enough to clean up the signal. I guess the bench surface was reflecting the signal to PLO3. Since things seem to be working I went ahead and attached the shields. The shielding method I came up with is removable so if I need to access the board for any reason it is not trouble.

I don't recall doing a 15 kHz NDK filter, but maybe I did. You seem to have an awful lot of ripple in the passband, suggesting that the impedance match is not quite right. What are you using? If the seller is correct about the 2k impedance, you should have a 47 pF shunt cap on each side, and 4.7 uH inductors leading from there to input/output. If your inductors are not toroids, you might have a Q problem.

8513. Re: [spectrumanalyzer] Filter Ripple

Yahoo group: spectrumanalyzer (2011)
Date: 2011-09-23 18:37:09 UTC
From: Eric Nystrom
Topic: 8476 Message: 8513

Sam,

Thanks for the comments. I thought the ripple did look bad, but was debugging other things.

I used 33 pf plus a trimmer. I have not spend much time adjusting yet.
The inductors are 0805 inductors. I guess I need to make some small toroids instead and give that a try.

This is what I found in the archived emails

For narrower
filters, a simple way to get started is to buy a canned filter on eBay, such as this one:

<http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=150546045545&ssPageName=STRK:MEWAX:IT>

eBay filters don't
always specify the terminating impedance, but this one does. The termination is specified as 2000 ohms, which you would match to 50 ohms with 4.7 uH inductors leading to the filter terminals and 47 pF capacitance shunt to ground from the terminals. To allow some tuning, use 33 pF capacitors and a small trimmer that goes to 25 pF or so. You don't need any equipment to tune it other than the MSA. Just install it as the RBW filter, and do a sweep with center=0 and span=0.02 MHz and you should get a nice graph of the top 50 dB or so of its response, which is all you need for tuning. Adjust the trimmers until the top of the response looks good.

For a PCB, you can
use a blank double-sided board. Drill holes for the terminals and for a few ground vias. Mount the filter on the bottom and solder its case to ground. Put the components on the top with a fence running across the middle of the filter to isolate the input and output. Solder a fence around the outside of the board and solder a lid on it to cover the components. (If the fence is soldered to both the top and bottom ground planes, you can skip the ground vias described above.) It is not critical to solder the lid to the isolation fence in the middle of the filter. Poke/drill/cut two holes in the lid so you can tune the trimmers. You can cover the holes later with copper tape (or tack on a piece of brass), though it doesn't seem to cause any harm to leave them open.

I forgot the SMA
connectors. Poke holes in the enclosing fence and solder the connectors to the fence with the center pin poking through the hole. A filter built with a similar approach is shown here:

<http://groups.yahoo.com/group/spectrumanalyzer/photos/album/271352628/pic/664919547/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc>

Double click just on the outside of the axis and its window will open. Change the top and bottom references. For example, with 10 horizontal grids, make to top reference 10 db higher than the bottom reference. It will then be 1 dB per grid. You can use any values, but the Top must be greater (in dB) than the Bottom. (Top = -15, Bot = -25)

Sam,

The inductor I used in the matching network is a

http://search.digikey.com/scripts/DkSearch/dksus.dll?Detail&name=445-1055-1-ND

It has a Q of 45 at 10 MHz. Is that reasonable?

I don't have the fence in the module either. I will try that and also try adjusting the trimmers
to see if that will improve things any.

8517. Re: Filter Ripple

Yahoo group: spectrumanalyzer (2011)
Date: 2011-09-23 23:46:31 UTC
From: Sam
Topic: 8476 Message: 8517

That Q value is great, and as it turns out it was measured at almost exactly our frequency. Fencing shouldn't affect the pass band response, just the far-out attenuation. As I recall, I always found that the proper capacitance was somewhat below the theoretical. It may also be that the filter impedance is not what the seller believes.

Scotty,
I did not explain myself properly.
What I am looking for is to change the vertical sensitivity. Right now the displayed 10dB increment equals about 14dB actual level change. I am looking for a simple way to modify this value without having to go through a calibration.
I am not ready for final system calibration since I don't have all the modules ready but would like to change the vertical axis gain for reference purposes.

Thank you, Jurgen

Jurgen,
If you don't want to do the calibration procedure yet, you can just enter two signals whose strength you know approximately and look at Show Variables to see what ADC reading they produce. Then manually enter those in the calibration file for the path you are using, in place of the default values. You put the weaker signal on one line and the stronger one on the next line, with the ADC reading first and the dBm value second. That will at least give you decent readings between those values. If the two signals are close in strength, you can manually extrapolate to what the readings would be at, say, 0 dBm and -100 dBm, and enter those values in the file.

8521. Cavity filter coupling loop location

Yahoo group: spectrumanalyzer (2011)
Date: 2011-09-26 19:32:29 UTC
From: jghbeta
Topic: 8521 Message: 8521

The coupling loop entry point ois specified at 70 mils from the bottom. How is this dimension arrived at and how does it affect filter behaviour? How critical is it?
The resonators are described as having 85 ohms impedance in general agreement with WB8GXB's indication. Shouldn't we try to get as close as 50 ohms to match with the mixers?

Topic: 8521 Message: 8522

The area enclosed by the coupling loops determines the amount of magnetic coupling, so if you make it longer you get more coupling, unless you also make it tighter to the wall.

Too much coupling gives a broadened response; way too much can actually create a dip in the middle. Too little gives a fairly sharp response, but with too much insertion loss. If you could view the change in response as you go from low coupling to high, you would see the profile move upward without changing shape, then start to become broader and flatter at the top without the top actually moving upward any more, as though it hit an invisible ceiling.

I suspect that there is more error caused by the loop bending away from the wall than from the loop being the wrong length.

75-85 ohms seems to be the sweet spot for minimizing loss in a cavity. (I believe that is also the reason TV cable is 75 ohms rather than 50.) The actual impedance seen from outside depends on the amount of coupling, so it can be near 50 ohms even if the cavity itself is 85 ohms.

Hello Everyone,
I am interested in this project as it has some (actually a LOT!) features that cost more than my car!

Where can I find schematics, parts lists etc?
Is there a central repository for this information?

I do appreciate everyones help and support.

Tnx,

Terry K9HA

Scotty's web site (in Links section) has all the schematics and info. In the Files section there is a document called MSA Overview that should help get you oriented.

8526. Mixer Tests and PDM Test

Yahoo group: spectrumanalyzer (2011)
Date: 2011-09-28 17:52:33 UTC
From: Eric Nystrom
Topic: 8526 Message: 8526

I have added some photos to the following album showing the results of my mixer tests and PDM test.

http://groups.yahoo.com/group/spectrumanalyzer/photos/album/80349892/pic/list

The input to the mixers is in the following files:

Master Osc output level
DDS 1 output after filter

The outputs of the mixers are in

Mixer x test

I have read through the test procedure and my interpretation is the conversion loss on the mixers is outside of the expected limit. I hope I have posted enough info to tell if this is the correct interpretation.

I have also posted a photo showing the results of the PDM test. It appears the output level is low based upon what is stated in the test procedure. I was wondering if the phase plot is reasonable? On port 2 of the control module bits 6 and 7 are bad. I did not want to wait to get a new chip so I moved the PDM control line to bit 5. I think I found all the places.

Thanks,

Eric Nystrom

Hi Eric,
 I believe you stated in an earlier post that you have not calibrated yet. If this is still true, don't take your conversion loss results too seriously. Also, you should use much lower input power to a mixer. An input level of greater than 0 dBm will likely cause the mixer to compress. I like around -10 to -20 dBm as an input level.
 Your picture showing phase vs frequency is inverted. Perhaps you have accidentally swapped the two inputs to the PDM.

Scotty,

Thanks for your comments.

For the mixer tests, is the coarse calibration outlined in the DDS test adequate to get reasonable
results? I did this calibration, but will double check it and retest the mixers.

On the levels to the mixer the test procedure shows connecting the Master Oscillator directly to the L port
through a DC block. This would put about 9.5 - 2.5 = 7 db to the L port. The ADE-11X+ data sheet shows
roughly this level on the plot for the L port.

The DDS 1 filter output is about -12 db which is what you used in the test procedure example.

Does this seem correct.

One thing I noticed was the output levels that I measured in the PLO power tests were consistent with
your examples in the test procedure while the mixer tests came out low.

On the inversion of the phase vs frequency I found the trouble. I rearranged the layout and built it according
to the diagram on this page

http://www.scottyspectrumanalyzer.com/msaslim.html#Block_Diagram_of_SLIM_MSA

I compared that to cable drawing on this page

http://www.scottyspectrumanalyzer.com/msaslim.html#Layout_of_the_MSA

and it appears that J1 and J2 are swapped on the Block diagram compared to the Layout drawing.

8530. Cavity Filter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-09-29 22:18:19 UTC
From: Eric Nystrom
Topic: 11 Message: 8530

Sorry for more questions.

I started testing my cavity filter and it seems to work, but there is an extra peak in the plot
about 15 db below the main peak and about 3 Mhz above the main peak that does not move
when I adjust the tuning screws. Only a rough calibration has been done, but the insertion loss
appears to be about 10db. The top is currently held in place with rubber bands. I wanted to
keep my options open for adjusting the wires if necessary.

I have included views of VNA mode, TG mode, and theinput signal plot.

Any ideas as to the cause of the extra peak? Would soldering the top help? Or should I try again.

Hi Eric,
 For the Mixer tests you do not use the DDS 1 filter output (J4). You use the "Spare" output (J3). It's output level should be about -8 dBm. It passes through the Final Crystal Filter and depending on its insertion loss, a total of -12 dBm entering the Mixer J2 port is reasonable.
Course calibration should give results that have less than a 10% error.
 I would not be concerned if the Mixer conversion loss is 8dB or less. If all 4 Mixers show the same results of excess conversion loss, the LO power may be lower than expected (Mixer J1).

The Block Diagram is correct. The "Proposed Layout" is not. It was not meant to be a guide for connecting specific I/O's.

Hi Eric,
 Good screen captures, showing a problem with the cavity filter. If that peak does not move when tuning the screws, there is a mechanical problem. Perhaps a bad solder joint on on of the hair pins. Perhaps one of the tuning screws is touching its center stub.

That peak at +3MHz looks like what you get with one of the four cavities out of tune, and you should be able to slide it downward by moving its screw inward. You also have a broad but small bump at about -4MHz that I would guess is another cavity out of tune. The lack of response when turning screws is odd. If the screws extend into the cavity, any change should have some visible effect unless the peak corresponding to the cavity being tuned is "off-screen". Be sure the screws are reasonably aligned with the ends of the resonator rods. Soldering is necessary for stability, but it should be possible with rubber bands to get basic functionality.

Scotty,

It was a bad solder joint on one of the hair pins. I fluxed, reheated and added some more solder
and I get the following results in TG Mode and VNA Mode. That was after a quick tune.

Thanks for the help.

Eric Nystrom

Subject: Re: [spectrumanalyzer] Cavity Filter

Hi Eric,
 Good screen captures, showing a problem with the cavity filter. If that peak does not move when tuning the screws, there is a mechanical problem. Perhaps a bad solder joint on on of the hair pins. Perhaps one of the tuning screws is touching its center stub.

8535. Re: [spectrumanalyzer] Mixer Tests and PDM Test

Yahoo group: spectrumanalyzer (2011)
Date: 2011-09-29 23:28:43 UTC
From: Eric Nystrom
Topic: 8526 Message: 8535

Scotty,

I am using the spare output of DDS1. My trace showed the output of DDS spare after the 10.7
MHz Filter. I have about -11 db going in to Mixer 2 and -21 db coming out. All the mixers appear low by about the same amount.

I have added a photo showing the PDM connections the way it is currently. I swapped it since
the previous trace. The Filter VNA trace shows how the phase currently looks. Does this look
correct now? Or was the inverted phase caused by something else possibly?

Thanks.

Eric Nystrom

Subject: Re: [spectrumanalyzer] Mixer Tests and PDM Test

Hi Eric,
 For the Mixer tests you do not use the DDS 1 filter output (J4). You use the "Spare" output (J3). It's output level should be about -8 dBm. It passes through the Final Crystal Filter and depending on its insertion loss, a total of -12 dBm entering the Mixer J2 port is reasonable.
Course calibration should give results that have less than a 10% error.
 I would not be concerned if the Mixer conversion loss is 8dB or less. If all 4 Mixers show the same results of excess conversion loss, the LO power may be lower than expected (Mixer J1).

The Block Diagram is correct. The "Proposed Layout" is not. It was not meant to be a guide for connecting specific I/O's.

Hi Eric,
 The phase slope is correct now.
I doubt if that high conversion loss is real. It is probably due to the "coarse" calibration.

Scotty,
Thanks for your comments.

For the mixer tests, is the coarse calibration outlined in the DDS test adequate to get reasonableresults? I did this calibration, but will double check it and retest the mixers.

On the levels to the mixer the test procedure shows connecting the Master Oscillator directly to the L portthrough a DC block. This would put about 9.5 - 2.5 = 7 db to the L port. The ADE-11X+ data sheet showsroughly this level on the plot for the L port.

The DDS 1 filter output is about -12 db which is what you used in
the test procedure example.
Does this seem correct.
One thing I noticed was the output levels that I measured in the PLO power tests were consistent withyour examples in the test procedure while the mixer tests came out low.

On the inversion of the phase vs frequency I found the trouble. I rearranged the layout and built it accordingto the diagram on this page
http://www.scottyspectrumanalyzer.com/msaslim.html#Block_Diagram_of_SLIM_MSA
I compared that to cable drawing on this page
http://www.scottyspectrumanalyzer.com/msaslim.html#Layout_of_the_MSA
and it appears that J1 and J2 are
swapped on the Block diagram compared to the Layout drawing. Eric Nystrom

I have added some photos to the following album showing the results ofmy mixer tests and PDM test.
http://groups.yahoo.com/group/spectrumanalyzer/photos/album/80349892/pic/list

The input to the mixers is in the following files:

Master Osc output level
DDS 1 output after filter

The outputs of the mixers are in

Mixer x test

I have read through the test procedure and my interpretation is the conversion loss on the mixers is outside of the expected limit. I hope I have posted enough info to tell if this is the correct interpretation.

I have also posted a photo showing the results of the PDM test. It appears the output level is low based upon what is stated in the test procedure. I was wondering if the
phase plot is reasonable? On port 2 of the control module bits 6 and 7 are bad. I did not want to wait to get a new chip so I moved the PDM control line to bit 5. I think I found all the places.

Thanks,

Eric Nystrom

8537. MSA filter plus PWB

Yahoo group: spectrumanalyzer (2011)

Topic: 8537 Message: 8537

A question regarding the MSA filter plus PWB from earlier this year.

There are four unlabeled, rectangular shaped PWBs included on the PWB. Each is about 3/8in X 1 1/8in in dimension. Each appears to to accommodate an SMA connector on each end. What are these four?

Thanks.

I don't recall exactly, but those are either for attenuators, or if they have a straight through connection they are intended to have the trace cut wherever necessary to add components for whatever you want--such as a series capacitor for a DC block.

Scotty,

I have two SLIM IF amplifier PWB's which are marked REV B. The web page for that module has details regarding REV A, but I see nothing about REV B.

Is there information about REV B out there on the web somewhere? What did REV B do to the module?

Thanks.

Hi Steve,
 The "official released" pwb on the web page is marked PWB-RFA Rev 0. Any other markings mean that someone has recreated the pwb and changed the nomenclature.
  The completed module would be "SLIM-IFA-33 Rev A". There is no Rev B.
Don't fret, just compare your pwb to the one on the web page. It is probably the same.

Scotty,

I got the quantity wrong in my first note -- I only have one of the REV B boards. It has silk screening and solder mask, I think the only MSA PWB's I have with those features came from Cash Olsen in 2008.

I did compare the REV B board with REV 0 and can find no differences on the trace/component side of the PWB. The bottom side has some solder mask that was evidently placed there as a place for silk screening to identify J1, J2, J3, J4 and P1. I believe the two boards are electrically identical.

Thanks for the advice.

Hi,

I ve got a moderate experience in hardware design , mostly DC circuits & PCB layout tools like Altium & Allegro,And have done some multi layerd & impedance controlled RF boards myself.But not that much in big scale either..
Ive got some exposure to testing with spectrum analyser,VNA & some little RF circuits too in my work place, but those equipments are not accessible for personal purposes..

So im interested in building an MSA.

Can some one guide me how to begin.?I ve read in the web pages that its better to start with control board first...
At my home i ve nothing but a Digital Multimeter at my hand..How should i start working on this?

Thanks for any help :)
Stephen.

See Message 8524 for starters.

As far as equipment, I strongly suggest you get an oscilloscope. Not only is it helpful in testing the MSA, but in general an oscilloscope has a much better cost/benefit ratio than a spectrum analyzer. Scotty will probably disagree with that statement.

I totally agree with Sam.

especially when totally adequate DSO's (Digital Storage Oscilloscope) have become as cheap as they are.

My pennies worth.
I would first borrow/share/buy a crude basic $1K SA 1.3Ghz with TG and a $100 2GHz counter
My 400 MHz digital Tex scope?was mostly useless in the RF area.
Even a basic 20 MHz scope would have been?enough for the control part.

Regards
Len Spyker

It is quite a conundrum. The perfect tool for building/testing an MSA is a calibrated MSA.
One of the building procedures that Scotty has on his website is laid out so you can
use previously built modules to check the new ones as you build them.
"Test as you build".

Here is the link:

http://scottyspectrumanalyzer.com/testingslim.html

A Volt-Ohm meter is required. An Oscilloscope is optional, but like Len said unless you have a
really fast one it is only really useful on the control side.

Have Fun,

Bob K6GGO

I have a 400 MHz Tektronix analog scope that came in very handy when building the MSA. It is useful for every module that operates at the IF frequency, or for looking at DDS outputs or the master oscillator. Obviously it does not help with the PLOs, though you can use it to look at the output of a mixer when the LO and RF are at nearby frequencies, even though they are >1 GHz. A 100 MHz scope would be almost as good, except for the MO.

You don't absolutely need a scope to build the MSA, but if you run into problems, nothing beats being able to look at actual waveforms.

If space is more of an issue than money, check out the Picoscope products, which are very nice and consist of a tiny box that interfaces with the computer.

I have been considering a pico 3206 scope.

Does any one have experience with the 3206?
How well does the digital scope perform?
Also, Spectrum Analyzer?

I'm looking at it for 2meter(150MHz) measurements.
Is it suitable for testing the MO?

Other than using a basic multimeter to check supply voltages, I didn't have or use any other test equipment to get my MSA going.

If you are very careful in the building, it will work first time and most alignment can be done using the MSA itself.

I did have a problem with the phase detector which I think was down to a badly soldered joint on that very small IC. I did use a 60MHz dual beam scope to find that but it was an old basic scope. No fancy storage facilities.

Geoff

Subject: Re: [spectrumanalyzer] Re: Hi newbie interested in MSA,How to begin??

It is quite a conundrum. The perfect tool for building/testing an MSA is a calibrated MSA. One of the building procedures that Scotty has on his website is laid out so you can use previously built modules to check the new ones as you build them. "Test as you build".

Here is the link:

http://scottyspectrumanalyzer.com/testingslim.html

A Volt-Ohm meter is required. An Oscilloscope is optional, but like Len said unless you have a
really fast one it is only really useful on the control side.

Have Fun,

Bob K6GGO

My pennies worth.
I would first borrow/share/buy a crude basic $1K SA 1.3Ghz with TG and a $100 2GHz counter
My 400 MHz digital Tex scope was mostly useless in the RF area.
Even a basic 20 MHz scope would have been enough for the control part.

Regards
Len Spyker

Also take a look at the BitScope. I have owned one for years and I am very
happy with it.

I have an older Pico scope, which functions well. The software is very good. However, a caveat on digital scopes: Aliasing causes signals whose frequency is more than half the sampling rate to appear on the screen, which means you need to filter out high frequencies. The fact that you can't make a brick wall filter means you could lose some of the high end of your bandwidth. However, the 3206 states a bandwidth of 200 MHz and sampling of 500 MS/s, so it might be feasible to make a filter that attenuates 250 MHz and above but does not affect 200 MHz very much; and maybe it even has a built-in filter. Plus, for repetitive signals the scope has an ETS mode that greatly increases the effective sampling rate. This scope should work fine at 150 MHz, though with a 200 MHz bandwidth it of course won't show harmonics, so it is useless for looking at distortion of a 150 MHz signal. It would work with the MO to show the basic functionality of the MO, but would not respond past the third harmonic and therefore won't show a true square wave--just a somewhat squashed sine wave.

The usefulness of the Picoscope 3206 as a spectrum analyzer is limited by its 8-bit resolution, though Pico claims it can achieve effective 12-bit resolution by making multiple measurements. I haven't tried that.

The real advantage of digital scopes is the ability to record data, which is especially handy for non-repetitive signals. For example, even for a simple operation like toggling the latch bits, the control board outputs have erratic spacing due to the computer's unpredictable time response. It's hard to get an analog scope to lock properly and show a consistent image, but a digital scope could just record a long sequence of the control board output. Of course, you would only be recording one bit at a time, but this might be useful for looking at glitches on the clock line.

For repetitive signals, like the MO, a DDS at a fixed frequency, or a 150 MHz oscillator, I much prefer an analog scope. If desired, you can "record" the data by taking a photo. My 400 MHz Tektronix (465? I can't recall) does a fine job and will easily measure a number of things like peak voltage, frequency, rise/fall time and time intervals. And if it encounters a signal of 500 MHz, it simply displays it as an attenuated signal rather than aliasing it to a lower frequency. I think it cost me $300-$400 years ago on eBay.

Another application of the scope: The MSA in reflection mode measures what sometimes seems like a mystical quantity called reflection coefficient. With a simple setup with a moderate bandwidth scope, you can actually see the reflections, which helps make them into something "real". See:
<http://www.wetterlin.org/sam/Reflection/VisibleReflections.pdf>

That document shows square wave reflections. Square waves are easy to interpret even with the reflection superimposed on the input signal; sine waves would be tougher. With a good reflection bridge and a dual-trace scope (like my Tektronix, though lower bandwidth may be fine), you could easily view a sine wave input signal on one trace and the reflection on the other. By comparing the amplitudes and phases, you could easily determine the reflection coefficient from the scope display--no VNA required. This should work quite well at any frequency within the bandwidth of the scope, with perhaps a practical upper limit of 100 MHz.

8554. USB Controller driver and programming

Yahoo group: spectrumanalyzer (2011)
Date: 2011-10-09 06:00:22 UTC
From: William Dillon
Topic: 8554 Message: 8554

Hi all,

I've got my custom USB control board booted and attached to Windows XP. I've followed the instructions in the "configuring USB adapter and installing drviers v2-0.doc" document, but I'm stuck on step 8 or 9 on the "New drivers" step by step section. First of all, in step 8, there isn't a "N2PK" option. There are variations of N2PK, version 2, version 5, 500mA, etc., but I don't know which to choose. When I choose one, and follow step 9 which is to unplug the USB and plug it back in, Windows doesn't ask for new drivers! What's the deal? Is there something I'm missing? Doesn't windows pick drivers based on the VID and PID? Don't those remain static?

Thanks for your help!
- Will

P.S. For anyone that mentioned being interested in this board when I posted about it earlier, I'm going to mail them out now that it appears that it works O.K. If you send me an email with your address I'll send one. It would be nice to receive a small donation on by blog if you like it, but that's up to you. Remember that it's not the larger Cypress chip, so it's limited a little.

Hi Will,
 The USB installation instructions are not exact for MSA. Both Jim and I had difficulty. When using the "N2PK VNA Interface Control" window, some of the differences you want to see are:
In the Setup Tab:
USB Driver name should be "MSA USB device 0"
Bend_Ax filename should be "....\Vend_Ax.hex"
Configuration String should be "MSA FW"
Interface Type should check the MSA button.
In step:
8. In the "Write EEPROM" field of the same tab, select the "MSA USB Version..." option from the drop-down list and click "Write Data". That should result in a success message, and the EEPROM will have been programmed. Now click the "Read" button and check that it reads back the same string that was programmed in (see "Data to be written" at bottom of tab).

The version depends on using the Control Board or USB Stand-Alone.

This installation will operate the MSA using Version 116 and the beta MSA Software. However, there are a few bugs in both.

 The smaller Cypress chip is no problem. The small Cypress driving the SLIM Control Board will provide plenty of I/O's for now and in the future.

I've figured it out!

In the instructions, it says to unplug the USB and plug it back in. This is O.K. if the device is bus powered, but because the USB control boards are self powered, you have to unplug it from power. Unplugging the USB doesn't really have any effect.

Will,

After you get the driver sorted out, when you get to the point of running the MSA program with USB, remember to have in the MSA_Software directory both the msadll.dll and msadll.lib files.

Regarding the Cytrix chip size, you need ports A (accessed by the ADC), B and D (both accessed by the other SLIM modules) and C (used by the switches: video, band and external bridge). I don't think the small chip has all four.

Jim,

Thanks! I've gotten to the point that the MSA software _seems_ happy. I've had it say "the USB thing is either disconnected, or too old" and I figured that out, now it just starts. The problem now is that none of the I/O lines on the cypress do anything. I've hooked them up to a logic analyzer and I haven't seen any activity during restart, scan, etc. What is a good testing procedure for this? By the way, I've also set the control board setting in the hardware config manager to "(3) USB".

I discovered the limitation of the chip well after the board was designed. I don't have an electronically controlled video switch, band switch, or bridge, so, for now, I'm O.K. with the smaller device. Later, after I verify other parts of the design (high voltage supply, SLIM header wiring, etc.) I'll make a new one with the larger device.

Thanks again!
- Will

8559. Re: [spectrumanalyzer] USB Controller driver and programming

Yahoo group: spectrumanalyzer (2011)
Date: 2011-10-10 16:23:35 UTC
From: william sprowls
Topic: 8554 Message: 8559

Hi Will,
 You can use the "usb configure.exe" to test your I/O's.
Open it and in the tab:Communicate with Adapter,
click "Check VNA interface".
The Messages should print out
Usb Interface String Identifier : index=1 :Cypress
Usb Interface String Identifier : index=2 :MSA FWP
Endpoint: 1, Type BLK, Endpoint 2 OUT Max Packet Size 0x200
Endpoint: 2, Type BLK, Endpoint 6 IN Max Packet Size 0x200
MSA USB Interface Found
(or something to this effect, since I have the larger Cypress)

Now, click "Build Raw Message"
the window, "Set Port Lines" will open
Click Set Port B
change the value from 0x00 to 0x01
OK
window closes
The Raw Message will now show:
A6 02 00 01 00 00 00
click button, Write VNA Interface
On the Cypress chip, the Port B, bit 0 will go High.
You can highlight and change the A6 02 00 01 00 00 00 to A6 02 00 00 00 00 00, click Write VNA Interface, and the line should go Low.
Ta Da!

If you pass this test, your Cypress board is working and there may be something hosed with the MSA Configuration.

If you want, give me a phone call and we can work it out.
two one four, two two one, two two four zero
I also have Skype, user name:
wsprowls

Thanks Scotty!

I'll play around using your instructions for a while. If I continue to have trouble I'll try to get ahold of you over voice.

When I'm feeling more confident that I know what I'm doing, I'll write an article that brings together all of the steps in one place. By far the most trouble I've had was finding where the info was! :)

Hi Will,
 You can use the "usb configure.exe" to test your I/O's.
Open it and in the tab:Communicate with Adapter,
click "Check VNA interface".
The Messages should print out
Usb Interface String Identifier : index=1 :Cypress
Usb Interface String Identifier : index=2 :MSA FWP
Endpoint: 1, Type BLK, Endpoint 2 OUT Max Packet Size 0x200
Endpoint: 2, Type BLK, Endpoint 6 IN Max Packet Size 0x200
MSA USB Interface Found
(or something to this effect, since I have the larger Cypress)

Now, click "Build Raw Message"
the window, "Set Port Lines" will open
Click Set Port B
change the value from 0x00 to 0x01
OK
window closes
The Raw Message will now show:
A6 02 00 01 00 00 00
click button, Write VNA Interface
On the Cypress chip, the Port B, bit 0 will go High.
You can
highlight and change the A6 02 00 01 00 00 00 to A6 02 00 00 00 00 00, click Write VNA Interface, and the line should go Low.
Ta Da!

If you pass this test, your Cypress board is working and there may be something hosed with the MSA Configuration.

If you want, give me a phone call and we can work it out.
two one four, two two one, two two four zero
I also have Skype, user name:

Jim,
Thanks! I've gotten to the point that the MSA software _seems_ happy. I've had it say "the USB thing is either disconnected, or too old" and I figured that out, now it just starts. The problem now is that none of the I/O lines on the cypress do anything. I've hooked them up to a logic analyzer and I haven't seen any activity during restart, scan, etc. What is a good testing procedure for this? By the way, I've also set the control board setting in the hardware config manager to "(3) USB".
I discovered the limitation of the chip well after the board was designed. I don't have an electronically controlled video switch, band switch, or bridge, so, for now, I'm O.K. with the smaller device. Later, after I verify other parts of the design (high voltage supply, SLIM header wiring, etc.) I'll make a new one with the larger
device.
Thanks again!- Will

In the instructions, it says to unplug the USB and plug it back in. This is O.K. if the device is bus powered, but because the USB control boards are self powered, you have to unplug it from power. Unplugging the USB doesn't really have any effect.

Will,

Once you get past the usb-configure testing, if the Spectrum Analyzer software is taking to the Cypress chip, you should see the SERCLK signal on A6 and the DATACLK iin B0, These are always on if the software is running. You can either use a scope or a frequency counter to see them. Make sure, just in case, that you have a recent version of the MSA software.

Aaargh!

I got it working!!! And then, what did I do? I accidentally shorted RB0 to +10 volts and zapped the output! While I'm encouraged by it working, I'll have to wait a while to get a new cypress chip.

Sincere condolences for the untimely demise.
Look in eBay for EZ-USB FX2LP board.. It has the 128 pin chip. They ship
from China fairly quickly. You may have to touch up some of soldering. I
thought that mine was bad and a dry soldering tip fixed it.

Thanks for the idea, Jim

I definitely want to keep using my custom board, but eBay gives me an idea. If I can buy a board for the same price as the IC on DigiKey, I must be able to get an IC cheaper. Indeed I can, for about $5. I may buy 3 of them, because these chips seem to be very sensitive. I'm completely sure that working with the Microchip PIC for so long has spoiled me! You can abuse those chips in obscene ways without breaking them!

8566. MSA kits or complete set of boards for revision C

Yahoo group: spectrumanalyzer (2011)
Date: 2011-10-11 10:08:09 UTC
From: stacywilliams6908
Topic: 8566 Message: 8566

Hi all

Please can somebody kindly advise me if full kits including boards are still available to buy for the the MSA project. Any advice, at all, would be greatly appreciated regarding these first few tender steps of this project.

With kind regards.

Stacy

What is your custom board and what size chip are you using?
If you use a 56 pin chip you won't have PORTC which is required for the switches.

Hey Stacy

I don't think anyone is selling any kits at the moment. I myself bought the components at Digi-Key, Mini-Circuits and a local store.

In case you download pcbexpress and order a full panel of the needed PWB's with Scotty's pcb file (min order is two panels for a total of, was it $120 ?), I'd be happy to buy the extra panel from you.

Best regards

Chris

I have some fully functional, populated boards, including perimeter fence. Off-hand I recall the 4 mixers, PLO1, DDS1, MO, PDM and ADC. There may be more. Let me know if you are interested.

Hi.

I have done the download and, I will order the boards when funds are available. Would you like me to order you another set of boards as well? Because, I will keep both sets as I'm not good with SMT. However, let me know and, I will Let you know when I'm ready to make the order! We can make payments via Paypal when the time comes.

Are all the boards SMT?

hey!

I think the Control Board has DIL-type ICs and at least one TO220 package (the voltage regulator).

Please order a full set for me as well, if you don't mind mailing it to Finland. Paypal is fine by me.

Chris

8572. MSA Input Switch

Yahoo group: spectrumanalyzer (2011)
Date: 2011-10-11 15:00:11 UTC
From: Sam
Topic: 8572 Message: 8572

I have done various layouts for a transmission/reflection switch and for a forward/reverse switch. A while ago we did a group board of a "signal router" which contained a relay version of both switches. It worked very well, but the relays are now very hard to find.

I'm now taking a slightly different approach. I believe that the MSA needs an internal Input Switch, which can choose among three inputs: SA, VNA transmission and VNA reflection. I have designed a board that will do this, using edge-launch connectors so it can mount on the front panel with the three input connectors sticking out. The output of the board runs to Mixer 1. This avoids the nightmare of connectors and cables that switches can present. This board replaces the existing MSA Input connector. Any forward/reverse switching would then be done separately in an external box, perhaps with a bridge enclosed.

I haven't built this particular board, but Lin and I have tested various versions of the switches, so I expect this board will work well. Transmission-Reflection isolation should be at least 120 dB to 500 MHz. Above that we'll have to see, but I expect at least 95 dB at 1 GHz. It is only about 2" square. I plan to order a few of these. If anyone is interested in participating, let me know. Depending what boards we end up incorporating, it may cost about $70 plus $15 per board set, so the ultimate cost per user depends on the number of participants. The boards will not have solder mask or silk-screening.

There are actually two alternative versions of the board. They are described at: <http://groups.yahoo.com/group/spectrumanalyzer/files/MSA_Input_Switch.pdf>

One caveat for those outside the US: In the past I have mailed small boards first class USPS, and they took about one month to arrive at non-US destinations (even Canada). I later tried Priority Mail to Germany, which cost $15 and the package ended up being returned to me with no explanation. So I have bad experience with foreign shipping.

One version of the board requires a single 12V G6Z-1F-A relay that is currently available only at Arrow, though they have a huge quantity. I can easily revise the layout to use the G6Z-1FE-A (about US$5.00), which has a slightly different footprint and is more available at Mouser and Arrow. The remainder of the switching is done by several PE4251. That IC is available from Richardson and is incredibly cheap (about US$1.10).

This board will allow a bridge/DUT arrangement to be cabled together and connected to the transmission and reflection inputs, and the MSA will select the proper input when scanning. Switching between SA and VNA is less automated, requiring a hardware switch--not a big deal since the cabling would be different for the two modes anyway, so some manual intervention is always necessary.

It actually will be possible to connect two separate external signals to the "transmission" and "reflection" inputs and use them for SA mode, with automatic switching between them, if that serves any purpose.

Finally, the user can always use the "SA" input for either SA or VNA mode, and ignore the transmission and reflection inputs if desired.

Sam W.

8573. Re: [spectrumanalyzer] USB Controller driver and programming

Yah, it uses the smaller chip. I'm O.K. with it at the moment because I don't have any of those things anyway. Later, I'm going to enhance the design to include the larger one. I'm also thinking of galvanically isolating the USB interface from the MSA. The Cypress has 3.3v I/O and all the SLIMs have 5, so I can mediate that voltage difference and isolate noise by using opto-isolators. For now, though, I'm happy with the board I've got, I just need to quit frying chips!

- Will

b.t.w., my custom board is based off Dave Robert's design, but adds the high voltage supply off the SLIM-CB and breaks the outputs out into individual SLIM connectors. I like having simple wiring harnesses. These are 1-to-1.

From: william sprowls
Topic: 8554 Message: 8575

Hi All,
 In regards to Jim's comment about Port C of the Cypress chip.
I have made a decision regarding USB and the MSA. It should satisfy most MSA builders, but alas, not all.
 I am supporting the use of the 56 pin version of the Cypress. I am also supporting the capability of the Cypress to drive the SLIM Control Board, not for driving the SLIM Modules directly. For this, only Cypress Ports A, B and D are required.
 There are several reasons for my decision:
1. 95% of the MSA builders already have the SLIM Control Board in the building stage or in use. Many are looking to use their MSA with USB without major hardware reconfiguration (mainly, wiring).
2. The Cypress chip is not very rugged and really needs buffering to drive the MSA modules. The SLIM Control board already utilizes buffers. Designing a new buffer board is re-inventing the wheel.
3. There have already been a few pwb designs that use the 56 pin Cypress (Dave's V04). There are also a few varieties of the FX2 board (128 pin Cypress) on E-bay.They will all work with my scheme.
4. The USB board/SLIM Control Board combination (call it USB-SCB) will provide 32 output lines and 5 input lines. We have MSA module designs requiring a total of 22 outputs and 2 inputs. So there is room for expansion. If we really need more than 32, I can redesign the SLIM Control board for 56 outputs and 5 inputs.
5. Designing a pwb that uses the 128 pin Cypress is easy, but to solder one of these puppies is not.
6. A single USB command procedure for USB-SCB will minimize the effort to keep the software current.

 I am designing a SLIM pwb that contains the 56 pin Cypress and an LPT type D25 male connector that will directly mate with the SLIM Control Board. It is just a minor re-configuration of Dave's V04 design that was done for N2PK. For those who already have Dave's board, this new pwb can be sliced apart and the connector side be used as an interface between the V04 and the SLIM Control Board.

Here are a few other things I have planned.
The upcoming MSA Software version 116 will utilize this USB-SCB scheme. The following version 200 will be a software and hardware upgrade to allow faster sweeping for both Spectrum Analyzer and VNA. I am contemplating that it should support only the SLIM MSA and not the Original MSA.

Scotty

What is your custom board and what size chip are you using? If you use a 56 pin chip you won't have PORTC which is required for the switches. Jim W1JGH

Hi Will,
 You can use the "usb configure.exe" to test your I/O's.

Open it and in the tab:Communicate with Adapter,
click "Check VNA interface".
The Messages should print out
Usb Interface String Identifier : index=1 :Cypress
Usb Interface String Identifier : index=2 :MSA FWP

Endpoint: 1, Type BLK, Endpoint 2 OUT Max Packet Size 0x200
Endpoint: 2, Type BLK, Endpoint 6 IN Max Packet Size 0x200
MSA USB Interface Found
(or something to this effect, since I have the larger Cypress)

Now, click "Build Raw Message"
the window, "Set Port Lines" will open
Click Set Port B
change the value from 0x00 to 0x01
OK
window closes
The Raw Message will now show:
A6 02 00 01 00 00 00

click button, Write VNA Interface
On the Cypress chip, the Port B, bit 0 will go
High.
You can
highlight and change the A6 02 00 01 00 00 00 to A6 02 00 00 00 00 00, click Write VNA Interface, and the line should go Low.
Ta Da!

If you pass this test, your Cypress board is working and there may be something hosed with the MSA Configuration.

If you want, give me a phone call and we can work it out.
two one four, two two one, two two four zero

Jim,
Thanks! I've gotten to the point that the MSA software _seems_ happy. I've had it say "the USB thing is either disconnected, or too old" and I figured that out, now it just starts. The problem now is that none of the I/O lines on the cypress do anything. I've hooked them up to a logic analyzer and I haven't seen any activity during restart, scan, etc. What is a good testing procedure for this? By the way, I've also set the control

board setting in the hardware config manager to "(3) USB".

I discovered the limitation of the chip well after the board was designed. I don't have an electronically controlled video switch, band switch, or bridge, so, for now, I'm O.K. with the smaller device. Later, after I verify other parts of the design (high voltage supply, SLIM header wiring, etc.) I'll make a new one with the larger
device.
Thanks again!- Will

Hi Scotty,

Thanks for giving your vision for the project. It's nice to know which direction the bus is headed. Given this, I'm still likely to design a new board, even if it's just for myself. The reason is that I got really frustrated with the mess of digital wiring at the control board. I pulled my hair out too many times trying to figure out what was happening. I will essentially combine the logic buffers and cypress into a single board with HV supply. It is hugely important to me to have one header for one SLIM.

Like I said, it's O.K. if I'm only designing it for myself. Also, I know that when you go off the reservation with SLIMs that you're on your own.

> Hi All,
> In regards to Jim's comment about Port C of the Cypress chip.
> I have made a decision regarding USB and the MSA. It should satisfy most MSA builders, but alas, not all.
> I am supporting the use of the 56 pin version of the Cypress. I am also supporting the capability of the Cypress to drive the SLIM Control Board, not for driving the SLIM Modules directly. For this, only Cypress Ports A, B and D are required.
> There are several reasons for my decision:
> 1. 95% of the MSA builders already have the SLIM Control Board in the building stage or in use. Many are looking to use their MSA with USB without major hardware reconfiguration (mainly, wiring).
> 2. The Cypress chip is not very rugged and really needs buffering to drive the MSA modules. The SLIM Control board already utilizes buffers. Designing a new buffer board is re-inventing the wheel.
> 3. There have already been a few pwb designs that use the 56 pin Cypress (Dave's V04). There are also a few varieties of the FX2 board (128 pin Cypress) on E-bay.They will all work with my scheme.
> 4. The USB board/SLIM Control Board combination (call it USB-SCB) will provide 32 output lines and 5 input lines. We have MSA module designs requiring a total of 22 outputs and 2 inputs. So there is room for expansion. If we really need more than 32, I can redesign the SLIM Control board for 56 outputs and 5 inputs.
> 5. Designing a pwb that uses the 128 pin Cypress is easy, but to solder one of these puppies is not.
> 6. A single USB command procedure for USB-SCB will minimize the effort to keep the software current.
>
> I am designing a SLIM pwb that contains the 56 pin Cypress and an LPT type D25 male connector that will directly mate with the SLIM Control Board. It is just a minor re-configuration of Dave's V04 design that was done for N2PK. For those who already have Dave's board, this new pwb can be sliced apart and the connector side be used as an

interface between the V04 and the SLIM Control Board.
>
> Here are a few other things I have planned.
> The upcoming MSA Software version 116 will utilize this USB-SCB scheme. The following version 200 will be a software and hardware upgrade to allow faster sweeping for both Spectrum Analyzer and VNA. I am contemplating that it should support only the SLIM MSA and not the Original MSA.

Indeed I can, for about $5. I may buy 3 of them, because these chips seem to be very sensitive. I'm completely sure that working with the Microchip PIC for so long has spoiled me! You can abuse those chips in obscene ways without breaking them!

I've followed the instructions in the "configuring USB adapter and installing drviers v2-0.doc" document, but I'm stuck on step 8 or 9 on the "New drivers" step by step section. First of all, in step 8, there isn't a "N2PK" option. There are variations of N2PK, version 2, version 5, 500mA, etc., but I don't know which to choose. When I choose one, and follow step 9 which is to unplug the USB and plug it back in, Windows doesn't ask for new drivers! What's the deal? Is there something I'm missing? Doesn't windows pick drivers based on the VID and PID? Don't those remain static?

Hi Sam,

Count me in please.

I've had lots of PCBs posted to me here in Oz, and surface mail has taken 2-3 weeks.

Thanks,

davidh

>
> I haven't built this particular board, but Lin and I have tested various versions of the switches, so I expect this board will work well. Transmission-Reflection isolation should be at least 120 dB to 500 MHz. Above that we'll have to see, but I expect at least 95 dB at 1 GHz. It is only about 2" square. I plan to order a few of these. If anyone is interested in participating, let me know. Depending what boards we end up incorporating, it may cost about $70 plus $15 per board set, so the ultimate cost per user depends on the number of participants. The boards will not have solder mask or silk-screening.

Hi Eric, On the page:
http://scottyspectrumanalyzer.com/trouble.html
Look near the bottom of the page for "MSA Frequency Range Test" for Phase Plot.
 We don't do the Cavity Filter test in VNA Mode, the phase would not be viable.

Also, there are more plots on the page:
http://scottyspectrumanalyzer.com/functionvnatrans.html

Both of these pages can be accessed from the Main Page:
http://scottyspectrumanalyzer.com/

Scotty

Eric,
I don't have such a plot, but if you do a transmission scan (without a line calibration) with TG cabled to the MSA input, you should get lines that slope downward as frequency increases, hit the bottom, wrap to the top, continue downward.... If your phase is reversed the lines will slope upward. That is, phase should be decreasing (meaning more phase delay) as frequency increases.
Sam W.

> This board will allow a bridge/DUT arrangement to be cabled together and connected to the transmission and reflection inputs, and the MSA will select the proper input when scanning.

Switching between SA and VNA is less automated, requiring a hardware switch--not a big deal since the cabling would be different for the two modes anyway, so some manual intervention is always necessary.

Hi Sam,

+1 please count me in.
I agree with Loïc I've received the pcbs in time (~2/3 weeks for France), any lost mail, UPS has always done the job correctly, up to now...

Thanks.

Michel

Loic: Pls, ...I may have missed a thread or two here....

Are you'all again discussing the purchase of a complete set of PWBs for an MSA?

If so, ...how much for a complete set for me in Austin, TX?

Thank you.

Don

No, this is just for an input switch which is an add-on to the basic MSA. It's a single board, though I would include several alternative designs since that won't affect the cost much.

I suppose I should have directed the responses off-line. Anyone interested, including those who already responded, should send me an email with their mailing address. We definitely have enough interest to make this a "go".

Currently I have a layout with all PE4251 ICs and another that uses the PE4251 plus a single G6Z-1F-A or G6Z-1FE-A relay. The two relays have slightly different footprints but the layout will accommodate either one, requiring the user to cut one trace if the -1F-A is used. I assume most people will choose one version of the layout and just build one board. Personally, I prefer the relay version, though it is a tiny bit bigger.

I am thinking of including an ERA-33SM for the on-board amp, since it is the perfect amp for this purpose and would only cost about $2.50 if I order a bunch. The ERA and PCB should easily fit in a first class padded envelope.

It appears likely that the cost, including ERA, shipping and Paypal fee, will be about $25. These boards are a little more expensive than normal because they contain an incredible number of vias.

Sam W.

8597. Re: MSA Input Switch

Yahoo group: spectrumanalyzer (2011)
Date: 2011-10-14 01:34:26 UTC
From: Sam
Topic: 8572 Message: 8597

I have decided to add a Forward/Reverse (F/R) switch to the board. This contains four PE4251 switches, and actually can be configured for all sorts of switching uses, by changing the coax connections. As an F/R switch, it runs the test signal forward or backward through the DUT for testing in either direction. Unlike the Input Switch, which I view as internal to the MSA, the F/R switch in my vision would be external, perhaps combined with a directional coupler.

The amount of interest is sufficient that even with this additional circuit the cost per board will be close to my original estimate. Kudos to Australia for keeping the interest up!

These exact circuits have not yet been built, but I have spent considerable time designing and testing related circuits, and I also want to acknowledge the great cooperation of Lincheng Xiu (Lin), who when not rollerblading has done a great job of design review, construction and testing.

A reminder: if you don't send me your address by email, I can't count you as on board.

8598. USB Debugging

Yahoo group: spectrumanalyzer (2011)
Date: 2011-10-14 12:15:54 UTC
From: Eric Nystrom
Topic: 8598 Message: 8598

I am trying to get the USB interface to the MSA working. I have one of the

EZ USB boards from eBay and have successfully installed the drivers
and firmware. I have checked the outputs with a logic analyzer and everything
seems to be working. Outputs start when the MSA is run and stop when it
stops.

I am having trouble getting but zero readings from the A to D converter.
I tried a test with the board not connected to the MSA. I put a pull up tied to
3.3 v on PA4 and PA5. When I look at show variables, I get a reading of all zeros
for the Mag and Phase inputs.

Any ideas?

Eric Nystrom

first try forcing the input high and make sure you get all 1's out but don't destroy the ADC output line driver in doing so. Then put a scope on the acd control lines and make sure they clock correctly. You wil find logic analyser trace examples in the files area of the group

Dave,

Thanks for the reply.

I did force the input high with a pullup and still read all zeros in the MSA software. I checked
the ADC control lines and they are correct according to your document. I still need to make

some updates to my ADC board to change the drivers and put the correct pullups on so that
I can use it with the USB board.

8603. Input Switch and F/R Switch

Yahoo group: spectrumanalyzer (2011)
Date: 2011-10-14 21:30:48 UTC
From: Sam
Topic: 8603 Message: 8603

I have updated the description of the Input Switch:
<http://groups.yahoo.com/group/spectrumanalyzer/files/MSA_Input_Switch.pdf>

I have also added a description of the Forward/Reverse Switch, which has been added to the group buy board:
<http://groups.yahoo.com/group/spectrumanalyzer/files/MSA_FR_Switch_PE4251.pdf>

There are now about 30 participants, far more than I anticipated. I have an offer from the UK to handle the European distribution, which will be helpful. If someone could do Australia/New Zealand, that would also help. I am considering including the PE4251s for non-US buyers, because they are apparently awkward to acquire in many areas; that would only add about $6 to the cost. I thought about doing the same with the relay but that would mess up my simple shipping concept (first class padded envelope). But with a "local distributor" I could send a bigger package to that person and even do a customs form all legal-like.

I would be happy to handle VK/ZL shipments Sam, unless another VK slightly more centrally located steps forward. Not that the postage rates are likely to vary much within VK.

Hi Eric,
The ADC pullups for the MUN2211 buffers are located in the Control board, so when you disconnect from it you lose the pullups. That would explain why you are getting 0 volts. You should be abble to place 10k pullups on the ADC board although it takes some calistenics. The Cypress chip will tolerate 5 volts output from the buffers.

Rex,
Comcast blocks emails from ISPs known to generate a lot of spam; your provider must be on their list. I've only had one prior problem with legitimate email. You can post your address here if you want and I'll copy the address and delete the message.

I have just sent an email to everyone on my list. If you think you are on the list but don't get the email, let me know. I could easily have dropped a name or messed up the email address. This is a bit of an administrative challenge.

If you haven't signed up but want to, I'll accept more names through the end of Sunday, U.S. Central Standard Time. As of now we are at 35 participants, half U.S. and half non-U.S.

Sam,
I did not receive an e-mail from you but still would like to buy one of these PCBs. Thanks.

I have designed a board that will do this, using edge-launch connectors so it can mount on the front panel with the three input connectors sticking out. The output of the board runs to Mixer 1. This avoids the nightmare of connectors and cables that switches can present. This board replaces the existing MSA Input connector. Any forward/reverse switching would then be done separately in an external box, perhaps with a bridge enclosed.
> >
> > I haven't built this particular board, but Lin and I have tested various versions of the switches, so I expect this board will work well. Transmission-Reflection isolation should be at least 120 dB to 500 MHz. Above that we'll have to see, but I expect at least 95 dB at 1 GHz. It is only about 2" square. I plan to order a few of these. If anyone is interested in participating, let me know. Depending what boards we end up incorporating, it may cost about $70 plus $15 per board set, so the ultimate cost per user depends on the number of participants. The boards will not have solder mask or silk-screening.

Topic: 8603 Message: 8616

Here is the current plan. This is preliminary, so DON'T SEND MONEY YET.

For U.S. participants, the package will include one PCB and one ERA-33SM. Relay and PE4251's are not included. The PE4251 can easily be bought from rell.com. The relay can be bought from Mouser, Newark or Arrow. The cost will be $25.00 including shipping and Paypal fee.

For non-US participants, the above package will be provided plus 10 PE4251s and one G6Z-1-FE-A-12DC relay. The additional cost will be $21 for the extra parts; we still have to figure out shipping cost. We can't customize these orders because it will become a nightmare.

For Australia/New Zealand, I will ship to Bill Maxwell who will redistribute. For Europe, I will ship to Reid Campbell (UK). Those shipments will be by Priority Mail, so hopefully they will be speedy. It will somewhat pricey for each of those shipments, but that cost gets spread over 8-10 people.

Summary: I think this is where we will end up:

US Participants--$25 for PCB and ERA-33SM.

Australia/New Zealand/Europe--$46 for PCB, ERA-33SM, 10 PE4251s and one relay, plus cost of shipping from the "local distributor".

Other non-US--$46 for PCB, ERA-33SM, 10 PE4251s and one relay, plus cost of shipping from US if it is over a couple bucks.

Sam W.

From: neganur
Topic: 7133 Message: 8617

I was testing my DDS1 and DDS3 last night and encountered something similar. My U3 is NC7SZ04M5XCT-ND from Digi-Key.

DDS 1 Test (log detector connected to J4 with DC block):

1. Voltage at P1-2 = 9.96 V (+10 V +/- 0.1 V)
2. Voltage at U1-1 = 9.30 V
3. U1-3, U2-6, U2-11, U2-18, and U2-23 = 4.93 V (+5.0 V +/- 0.1 V)
4. U3-5 = 4.78 V (should be 30 mV lower than U1-3)
5. U3-2 = 2.40 V (It should be +2.5 volts, +/- .1 volts)
6. U2-3 and U2-4 = 4.92 V
7 U2-1, U2-2, U2-26, U2-27 and U2-28 = 0 V
8. U2-12 = 1.268 (should be +1.248 volts, +/- .01 volts)

DDS 1 Test (J4 floating):

1. Voltage at P1-2 = 9.96 V (+10 V +/- 0.1 V)
2. Voltage at U1-1 = 9.39 V
3. U1-3, U2-6, U2-11, U2-18, and U2-23 = 4.93 V (+5.0 V +/- 0.1 V)
4. U3-5 = 4.88 V (should be 30 mV lower than U1-3)
5. U3-2 = 2.448 V (It should be +2.5 volts, +/- .1 volts)
6. U2-3 and U2-4 = 4.93 V
7. U2-1, U2-2, U2-26, U2-27 and U2-28 = 0 V
8. 1.267 (should be +1.248 volts, +/- .01 volts)

With load: 15 mA
Without load: 5mA

I wonder if the voltages denoted in the DDS Module Test are for an unloaded Log Detector. Although the test specification asks to connect J4 to it via the DC block.

By the way,

" Run the MSA Program. The MSA Main Graph will open and sweep with the MSA in the Spectrum Analyzer mode."

Ver116, RevF doesn't do this. I have do select Mode->Spectrum Analyzer before it shows anything.

I repeated the test with DDS 3:

DDS 3 Test (log detector connected to J4 with DC block):

1. Voltage at P1-2 = 9.96 V (+10 V +/- 0.1 V)
2. Voltage at U1-1 = 9.28 V
3. U1-3, U2-6, U2-11, U2-18, and U2-23 = 4.93 V (+5.0 V +/- 0.1 V)
4. U3-5 = 4.78 V (should be 30 mV lower than U1-3)
5. U3-2 = 2.40 V (It should be +2.5 volts, +/- .1 volts)

6. U2-3 and U2-4 = 4.92 V
7 U2-1, U2-2, U2-26, U2-27 and U2-28 = 0 V
8. U2-12 = 1.260 (should be +1.248 volts, +/- .01 volts)

DDS 1 Test (J4 floating):

1. Voltage at P1-2 = 9.96 V (+10 V +/- 0.1 V)
2. Voltage at U1-1 = 9.39 V
3. U1-3, U2-6, U2-11, U2-18, and U2-23 = 4.93 V (+5.0 V +/- 0.1 V)
4. U3-5 = 4.88 V (should be 30 mV lower than U1-3)
5. U3-2 = 2.448 V (It should be +2.5 volts, +/- .1 volts)
6. U2-3 and U2-4 = 4.93 V
7. U2-1, U2-2, U2-26, U2-27 and U2-28 = 0 V
8. 1.267 (should be +1.248 volts, +/- .01 volts)

With load: 15 mA
Without load: 5mA

Best regards

Chris

8619. Re: [spectrumanalyzer] Re: DDS U3 current

Yahoo group: spectrumanalyzer (2011)
Date: 2011-10-17 13:45:26 UTC
From: william sprowls
Topic: 7133 Message: 8619

Hi Chris,
Your DDS testing prompts me to re-visit and update a few things. The voltages on the DDS schematic and the voltages used in the Test paragraphs are pretty old. The 3 ma current shown for the current to U3, was an original current verification when the DDS was "loaded" by the PLO module. At that time, the PLO "loading" was an unterminated line. U3 did not have the low pass filter in the output, either.
 It is now suggested in the documentation for the PLO to have a load of 50 ohms. This is the same load that is represented by the Log Detector and DC block. U3's low pass filter also increases U3 current. Therefore the real current for U3 should be about 12 ma, +/- 5 ma.
 Your measurements show that your DDS1 and DDS3 are performing well.
Scotty

I was testing my DDS1 and DDS3 last night and encountered something similar. My U3 is NC7SZ04M5XCT-ND from Digi-Key.

DDS 1 Test (log detector connected to J4 with DC block):

1. Voltage at P1-2 = 9.96 V (+10 V +/- 0.1 V)

2. Voltage at U1-1 = 9.30 V

3. U1-3, U2-6, U2-11, U2-18, and U2-23 = 4.93 V (+5.0 V +/- 0.1 V)

4. U3-5 = 4.78 V (should be 30 mV lower than U1-3)

5. U3-2 = 2.40 V (It should be +2.5 volts, +/- .1 volts)

6. U2-3 and U2-4 = 4.92 V

7 U2-1, U2-2, U2-26, U2-27 and U2-28 = 0 V

8. U2-12 = 1.268 (should be +1.248 volts, +/- .01 volts)

DDS 1 Test (J4 floating):

1. Voltage at P1-2 = 9.96 V (+10 V +/- 0.1 V)

2. Voltage at U1-1 = 9.39 V

3. U1-3, U2-6, U2-11, U2-18, and U2-23 = 4.93 V (+5.0 V +/- 0.1 V)

4. U3-5 = 4.88 V (should be 30 mV lower than U1-3)

5. U3-2 = 2.448 V (It should be +2.5 volts, +/- .1 volts)

6. U2-3 and U2-4 = 4.93 V

7. U2-1, U2-2, U2-26, U2-27 and U2-28 = 0 V

8. 1.267 (should be +1.248 volts, +/- .01 volts)

With load: 15 mA

Without load: 5mA

I wonder if the voltages denoted in the DDS Module Test are for an unloaded Log Detector. Although the test specification asks to connect J4 to it via the DC block.

By the way,

" Run the MSA Program. The MSA Main Graph will open and sweep with the MSA in the Spectrum Analyzer mode."

8620. PLO supply voltage

Yahoo group: spectrumanalyzer (2011)

From: Jurgen
Topic: 8620 Message: 8620

In one of the schematics the 5V regulator is replaced with a jumper.
I am running mine with a 6V regulator and am getting ~+7dBm out.
This is a bit low.
The ROS1500 absolute ROS1500 max ratings are +5V.
The jumper would raise Vcc to ~9.5V.
Has this change been generally implemented?
There is no mention in the change notes.

Thanks, Jurgen

Jurgen

I wonder if you are looking at the correct data sheet.

The ROS-1500+ (the + means it is a lead free device) has a DC operating power of 10 volts on Vcc with an absolute max supply of 11 volts on Vcc. The max tuning voltage is 22 volts on Vtune.

If by chance you are looking at ROS1500C device, then the Vcc is indeed 5 volts with a max tuning voltage of 7 volts.

It is only PLO2 that has the 5 volt regulator bypassed.

Keep building, it is all worth the effort.

Geoff

OK, therein is the problem. I did not look properly.
I am actually using the ROS-2150VW which is rated at absolute max of 6V.
My mistake.
I guess there is nothing more I can do to increase the output level.

Thanks, Jurgen

From: Sam
Topic: 8620 Message: 8623

To clarify, PLO1 and PLO3 use the ROS-2150VW operating at 5 or 6 volts. PLO2, which doesn't need the broad tuning range of the other two, uses the ROS-1500 which operates on 10 V and thus does not use the regulator. The PCB is the same for all three; it's just a question of how you populate it.

I don't think you'll have any problem operating with 7 dBm.

8624. Re: PLO 1 Debugging Update

Yahoo group: spectrumanalyzer (2011)
Date: 2011-10-23 17:38:36 UTC
From: neganur
Topic: 8476 Message: 8624

I had an awful lot of 76 mV peak to peak ripple on my +20V directly at the output pin of the control board (P23_2) which I was able to decrease to 10 mV pp by adding capacitors at C20, C21, C23, C24 and C25.

I then replaced the TC7662 with a TC7660 only to find that the ripple had increased to 44 mV pp, so I put the 7662 back. I then took an electrolytic low ESR capacitor, held it across all the capacitors in the voltage converter while watching the amplitude response in the MSA software, and found the best improvement at location C21.

Has this been an issue for anyone else?

I added some screen shots from the software and my oscilloscope in my album, since I could not find yours anymore.

http://groups.yahoo.com/group/spectrumanalyzer/photos/album/910808747/pic/list

My Voltage converter is not shielded at all by the way. It's a huge mess on my desk at the moment :)

Best regards

Chris

Chris,

I added an additional 10 uf at C46 on PLO1 and PLO3 boards.

Did you try that also?

Hi Eric,

yes, I did end up placing another 10uF on top of each C48 on the PLO 1 and 3 board. I'm down to 2 mVpp at the LT1677 but I am not quite satisfied. The problem is really at the output of the voltage converter. Would adding another 10 Ohm series resistor not be a better improvement than all those extra capacitors?

By the way, I got my hands on a couple of those NDK 10F15D filters. What values did you end up using for the matching components? 4.7uH and 33pF in parallel with a trimmer?

Chris,

Adding more resistance would drop the voltage further and might limit the tuning range. I don't
know if that would make a real difference or not. Are you using a linear or a switching supply
to power your MSA?

As to the filter. I am using the 4.7uf and 33pf with a trimmer, but it does not match the impedance
correctly for me. I need to work on that, but have not come up with any ideas yet. Do you have
access to other equipment that would allow you to determine the impedance of the filter?

Hey

I'm using a HP6632B linear power supply (0.3 mV ripple). I'm not sure what I will use once everything is ready.

Regarding the filters, I may be able to measure something but I have no idea how to interpret it :) I'm still a filter newbie but Sam and Scotty may be able to point me in the right direction. I remember Sam had some nice document on filters, I will read some more.

I have access to a couple of network and emc analysers and I'm learning how to use them at the moment. I managed to print some impedance response curves but I'm not sure if that helps us. On top of that, I forgot to mark which plot belonged to which filter...but I will upload the pictures anyway.

http://groups.yahoo.com/group/spectrumanalyzer/files/Crystal%20Filters%20RBW/

I measured a NDK 10F15D, NDK 10P7D and NDK 10P17D. They are all from ebay and the sellers seem to have a lot of them available.

I haven't been able to find datasheets for them but lots of filters are similar with similar markings.

I believe that the 10F15D has a Zin/out of 3kOhm-3.3kOhm, 0 pF.

Chris

Topic: 8476 Message: 8629

Be sure you are using X5R or X7R ceramic for the 10 uF caps; the cheaper types lose capacitance at high voltage. I believe others have gotten good results doubling up on the caps using the good-quality ones. One alternative is to build the 23V supply described on my web site. Its ripple is well below 1 mV.

Your impedance scans of the filters show that they are not being matched to 50 ohms. (I assume you scanned the input with a 50-ohm termination after the output impedance match--that termination might actually have been the VNA terminal used for transmission measurement.) Some pictures show a nice stable match, but at 100 ohms. Others show pretty erratic matching. The transmission has far too much ripple, which is due to the matching problem. I assume you are using an LC match, with the capacitor shunt to ground on each side of the filter (with trimmers parallel to those caps), and the inductor in series "outside" of the capacitor. Be sure you use an inductor with Q of at least 20 (25 or 30 is even better) measured near 10.7 MHz.

It is also possible that the filters don't actually have the impedance specified by the seller, or he may have mixed up which impedance goes with which bandwidth. You apparently have access to some sort of VNA. If you can create a Touchstone file of S21 and another of S11, you can load the data into the Two-Port Module of the MSA software (load S21 as S21 and S12 and load S11 as S11 and S22, to keep it simple), then open the Terminations window and use AutoMatch to calculate the impedance matching necessary for a simultaneous conjugate match. You can also do this auto matching with RFSim99, but you have to manually construct the two-port parameter file from the individual parameter files (unless your VNA does all four parameters at once.)

To be fancier, you could also measure S22 instead of just duplicating S11 as S22 (In theory S21=S12 so you can get by duplicating S21 to use for both values). In doing this with a ceramic filter specified as 330 ohms and 0 pF, I found that the reason the spec is 0 pF is not that the input and output have no reactance, but rather that it is not completely predictable and might be either capacitive or inductive, so the best they could do for a general spec is to say 0 pF.

Sam, Eric

just a short update, unfortunately my time is being sucked up by project work.

Thanks for you reply Sam! The document I remembered was "Impedance Matching of Filters with the MSA" and it is very useful.

I have recorded all four S parameters in touchstone format for all the filters I have during this week. It turned out to be difficult to get the data out of the machines since the only floppy drive that actually worked was of the analyser that apparently did not support the touchstone format. Long story short, I imported a lot of *.s1p files into the MSA software and used it to save the data as s2p files. I have uploaded most of the data to the files section.

http://groups.yahoo.com/group/spectrumanalyzer/files/Crystal%20Filters%20RBW/

I tried using RFsim99 but the application seems to complain about the files "invalid floating point operation". I The MSA software crashes often when I use the two-port matching on my Win7 machine. It runs just fine on my WinXP laptop though. I can provide error logs if you want.

Eric, I hope this helps you to find out what the matching circuit should be like.

I will write more later.

Chris

I believe others have gotten good results doubling up on the caps using the good-quality ones. One alternative is to build the 23V supply described on my web site. Its ripple is well below 1 mV.
>
> Your impedance scans of the filters show that they are not being matched to 50 ohms. (I assume you scanned the input with a 50-ohm termination after the output impedance match--that termination might actually have been the VNA terminal used for transmission measurement.) Some pictures show a nice stable match, but at 100 ohms. Others show pretty erratic matching. The transmission has far too much ripple, which is due to the matching problem. I assume you are using an LC match, with the capacitor shunt to ground on each side of the filter (with trimmers parallel to those caps), and the inductor in series "outside" of the capacitor. Be sure you use an inductor with Q of at least 20 (25 or 30 is even better) measured near 10.7 MHz.
>

> It is also possible that the filters don't actually have the impedance specified by the seller, or he may have mixed up which impedance goes with which bandwidth. You apparently have access to some sort of VNA. If you can create a Touchstone file of S21 and another of S11, you can load the data into the Two-Port Module of the MSA software (load S21 as S21 and S12 and load S11 as S11 and S22, to keep it simple), then open the Terminations window and use AutoMatch to calculate the impedance matching necessary for a simultaneous conjugate match. You can also do this auto matching with RFSim99, but you have to manually construct the two-port parameter file from the individual parameter files (unless your VNA does all four parameters at once.)
>
> To be fancier, you could also measure S22 instead of just duplicating S11 as S22 (In theory S21=S12 so you can get by duplicating S21 to use for both values). In doing this with a ceramic filter specified as 330 ohms and 0 pF, I found that the reason the spec is 0 pF is not that the input and output have no reactance, but rather that it is not completely predictable and might be either capacitive or inductive, so the best they could do for a general spec is to say 0 pF.

I looked at one of the s2p files. The frequency steps in 1 kHz increments but repeats many times before incrementing--and the data at the repeated frequency is not constant. I suspect what is happening is that the VNA is taking smaller steps but rounding off the frequency to the nearest kHz when it sends it to the file. This may be causing the errors, since Touchstone files are supposed to have the frequency increasing at every step.

Eric,

I was able to get a working match for the 11F15DG. I used 5.6uH and 33pF + a 5...30pF trimmer. Try RFsim99 with a Zin/out of 2.4kOhm/0pF.

Chris

Have a look at the MSA screenshot of the filter in the files section:

http://groups.yahoo.com/group/spectrumanalyzer/files/Crystal%20Filters%20RBW/NDK%2010F15D/

Oh that explains a lot. I noticed that the user interface was rounding to kHz while markers were displayed with 100 Hz resolution. I'll have a look in the manual since I can print single sheets of S21 data with 10 Hz resolution.

Thanks for the hint!

Sam,

I am going to start a new post about filters soon since it's unrelated to the PLO debugging.

Regarding the nice match at 100 ohms, could it be that the filter has an integrated matching transformer? I finally found a datasheet that looks like it contains the two filters with the 100 ohms impedance response.

The package is really big (D-100), approximately 1 x 1.5 x 0.5 inches

Chris

Topic: 7251 Message: 8636

Assuming your scan did not include any matching components, it does seem likely that the filter has some internal matching to a relatively low impedance. Your scan shows 100 ohms input impedance, but the scan would be done with 50 ohms on the output. A filter with impedance of 100 ohms should show 100 ohms input impedance with 100 ohms on the output, which suggests that yours has an actual impedance of something higher than 100 ohms.

Here is a possible solution. Take three entries from your s2p file near the filter center. Tweak the frequencies if necessary to make them ascending. Then make a new s2p file with just those entries. Use Auto Match in either the MSA software or RFSim99. That won't give you much of a graph, but it will give you the necessary matching components.

Sam W.

Hello Sam;

Just wondering if there might be a germ of an idea here where digitally programmable source and load resistances could be made created for looking at filters. Sort of like an attenuator but series resistance to be added on command to the 50 ohm source and same for the effective load resistance. Perhaps it would be better to start with a higher impedance and do these as shunts? Perhaps a transformer to 2k ohms up and down? Most of the filters are under 100 MHz, even a 50 MHz limit would be ok. Obviously the gain through the system changes with these ideas so some concept of calibration needs to go with the switches. Crazy? Anybody seen anything like this from a past life?

Regards;

Greg

8638. Crystal Filter Matching

Yahoo group: spectrumanalyzer (2011)
Date: 2011-10-29 17:23:18 UTC
From: william
Topic: 1255 Message: 8638

Hi All,
Since there have been some recent postings about crystal filter matching, this might be of some interest.
We often find really good deals on crystal filters on E-bay but there are a few things to consider.
1. Are these filters "over-runs"? Meaning, did the mfg make more than his customer needed and sold them to the E-bay vendor. If so, this is good. The best situation possible.
2. Are these filters "rejects"? Meaning, they failed one or more of the mfg's specifications. If a cosmetic defect, this is good. If the filter is out-of-spec electrically, this can be ok or bad, depending on the spec. that it failed.

And the one that is the most misunderstood:
3. Are these filters "deviants"? Meaning, the mfg modified one of their "standard" designs for a customer and these became "over-runs". This can be good, but the specifications may be entirely different than those for a "standard" filter. As an example, a mfg's "standard" filter had an unbalanced input and output (the most common configuration). But the "deviant" has a balanced input and output. The mfg would normally re-mark the "deviant" filter with a variant part number, but may still be very similar to the part number of the "standard". I cringe when someone says "use the spec for PN-XYZ for PN-XYz. They are similar so they must be the same." If a filter's part number cannot be 100% associated with its mfg's "standard" part number, it is a "deviant". And worse, the mfg will not give you its specs, due to contractual agreements between the mfg. and his original customer.

Over the years, I have seen "deviants" everywhere, not just in filters. They can be transistors, IC's, or anything. "Deviants" are not bad, they just need to be understood.

Greg,
That might be feasible. The complication would be that the response can be very sensitive to reactance, so you would need to be able to iterate through reactances as well.

This sort of iteration is what I originally expected to do in software for AutoMatch. Fortunately, however, it turns out there is a reasonably straightforward formula for finding the required in/out impedances for a simultaneous conjugate match, which I found in a text by Pozar. So the simplest method seems to be to determine the four S-parameters and apply the formula.

Sam W.

8640. Sam: PCB Filters as cavity filter replacement

Yahoo group: spectrumanalyzer (2011)
Date: 2011-10-29 23:50:33 UTC
From: Dan Andersson
Topic: 8640 Message: 8640

Sam,

I promised to come back after I tested the PCB filters as an option to cavity filters for 1013MHz.

I have been tied up with to much other stuff so I haven't been able to spend the time I needed fully out but...

The results are - forget it... At least for "normal deadly homebrewers with a budget".

I managed to make workable filters but only with a lot of hands on - on every filter I made.

I can make the filters with an accuracy (repeatability) of better than 0.0002" so accuracy
is not the problem, the laminate materials are, in combination with the enclosure.

I can make filters on PTFE laminates from Taconics, Rogers and so on. To make these work, I had to make
an alu enclosure with mounting ridges/fixtures so the PCB was forced into a specific position to end up
on the designed+hand tuned frequency as well as glued inplace with silver epoxy. These filters doesn't like the narrow bandwidth required and this showed to be the Achilles heal. Any deviation in the mounting inside the enclosure and the filter is off.

I can make "decent" filters on FR4 but with no way near the required bandwidth.

I did some cost/time breakdown and put simply, it's easier and cheaper to make cavity filters.
The size of a PCB filter is by all means smaller but it's not worth it.

Luckily, I have access to one of these horribly silly expensive softwares that can do microstrip filters at will. Still, the theoretical bandwidth is there but never in real life when put on test with my VNA.

It's a pity but it's just not a suitable solution.

I can of course send dimensions to anyone interested if they want to test by themselves. (unless everyone want it :)

With these tests in my rear mirror, I'm considering myself lucky not to have to work with filter design/production on a daily basis - I'd go bonkers!

I made 25-ish filters to verify the possibility to produce a batch of 1013MHz filters for the spectrum analyzer build but almost each of these filters behave slightly different...

I made 5+ filters for another ecm project and another frequency, but with a rather exotic (read as - expeeensive) PTFE/ceramic material. These worked out good but the bandwidth

wasn't as narrow.
(No, I can't show photo's of these - sorry)

But as I see in the group now, it looks like most of the specc builders are content with the cavity filter build.

I'm archiving this for now...

//Dan

Dan,
Thanks for the effort. It would have been great had it worked out. But the PCB filter idea may still be useful.

Let me point out something about bandwidth: You can make a very operational MSA with a pretty crummy bandwidth for the IF1 filter. The downside is the creation of images in SA mode. However, to get your MSA up and running well enough to test out the various modules, a PCB filter might do just fine. For example, if you want to view an oscillator signal, you could just ignore the image. For VNA purposes, such as scanning an RBW filter, I don't think the IF1 filter bandwidth has much relevance, if any.

I get the impression that the cavity filter is a roadblock for many people in getting started. Maybe it would be better to start with a simple filter and worry about the ultimate cavity filter when everything else is done. I operated for over a year with a low grade cavity filter until I got the final one done.

Ah, but Sam! You really only have two options. Build the cavity first so everything later seems like childs play, or build everything else first so you have so much invested you HAVE to do a cavity filter. In truth, and I have made a half dozen, and even scaled one to clean up a quadrupled 245 MHz OCXO for a clock for a AD9910 DDS. They aren't such a tough nut to crack. Particularly after the first one.

W4ZCB

I get the impression that the cavity filter is a roadblock for many people in getting started. Maybe it would be better to start with a simple filter and worry about the ultimate cavity filter when everything else is done. I operated for over a year with a low grade cavity filter until I got the final one done.

Well Sam,

I saw a UK company looking for a cavity filter engineer up in Necastle upon Thyne - and they paid double engineering wages for that position...

But as usual, if you made one or two, it becomes easier every time..

The softwares that can do this are way to complex to use. Propably written by boffins for other boffins...

I'd love to see a software where I can tell external sizes and restrictions, Centre freq, BW, filter linearity and attenuation >> The press a button and out pops a proper set of drawings...

But no. It works more or less this way with PCB filters but not for cavity filters.

I have some ecm stuff for 1275MHz and 1575MHz on order so I might give it another go as 1275 is not to far off and the process of building them should be able to re-size for 1013. We'll see.

Dan,

Have you tried the CQ filter type on page 37 of the document below?

http://maxwell.uwaterloo.ca/~myu/publications/WMB-9-color-Hong.pdf

It seems to have the desired narrow passband.

From the photos he has his example in a fancy box, and I suppose the
laminate is exotic.

Do programs like Sonnet model the effects of the enclosure accurately?

Subject: [spectrumanalyzer] Sam: PCB Filters as cavity filter replacement

Sam,

I promised to come back after I tested the PCB filters as an option to
cavity filters for 1013MHz.

I have been tied up with to much other stuff so I haven't been able to spend
the time I needed fully out but...

The results are - forget it... At least for "normal deadly homebrewers with
a budget".

I managed to make workable filters but only with a lot of hands on - on
every filter I made.

I can make the filters with an accuracy (repeatability) of better than
0.0002" so accuracy
is not the problem, the laminate materials are, in combination with the
enclosure.

I can make filters on PTFE laminates from Taconics, Rogers and so on. To
make these work, I had to make
an alu enclosure with mounting ridges/fixtures so the PCB was forced into a
specific position to end up
on the designed+hand tuned frequency as well as glued inplace with silver
epoxy. These filters doesn't like the narrow bandwidth required and this
showed to be the Achilles heal. Any deviation in the mounting inside the

enclosure and the filter is off.

I can make "decent" filters on FR4 but with no way near the required bandwidth.

I did some cost/time breakdown and put simply, it's easier and cheaper to make cavity filters.
The size of a PCB filter is by all means smaller but it's not worth it.

Luckily, I have access to one of these horribly silly expensive softwares that can do microstrip filters at will. Still, the theoretical bandwidth is there but never in real life when put on test with my VNA.

It's a pity but it's just not a suitable solution.

I can of course send dimensions to anyone interested if they want to test by themselves.
(unless everyone want it :)

With these tests in my rear mirror, I'm considering myself lucky not to have to work with filter design/production on a daily basis - I'd go bonkers!

I made 25-ish filters to verify the possibility to produce a batch of 1013MHz filters for the spectrum analyzer build but almost each of these filters behave slightly different...

I made 5+ filters for another ecm project and another frequency, but with a rather exotic (read as - expeeensive) PTFE/ceramic material. These worked out good but the bandwidth wasn't as narrow.
(No, I can't show photo's of these - sorry)

But as I see in the group now, it looks like most of the specc builders are content with the cavity filter build.

I'm archiving this for now...

That's exactly right. After building the modules you'll be motivated to do the cavity filter. I think the important thing is to get started and feel like you are making progress, and many builders can probably finish half the modules in the time it would take them to get pumped for doing the cavity filter.

Neil,

I don't theink the laminat is that exotic,only expensive :)

Yes, the CQ filter looks as it's possible to use. But! I wonder how many iterations he had running before the final target was reached?! It's OK to burn FR4 but I need to save my supply of Rogers... :)

FR4 works "fine" (umm! good enuf) up to 5-5 GHz unless you do demanding stuff like super stable vco's etc and - hrmmm, filters. But as Sam writes, keep the bandwidth a but wider and it's easier.

The CQ filter in the example neet to be a bit sharper to make SA people really happy.

I'll see if I can find the math for it.

Neil,

Enclosure effects? Yes and no. The softwares manage solid boxes with a decent prediction. But if you use the flyfy microwave "antibounce" stuff under the lid as I usually do, it requires testing. The sides proximity is more important than the height to the lid if you allow for 10+mm or so between the board and the lid. Make it 20mm with microwave foam and it'll still be predictable.

From: Len
Topic: 8640 Message: 8649

Hello Group

Look in the Len Spyker group files area and look for my spreadsheets on coaxial filters.

The coax filter design formulas in the spreadsheet are from a serious RF book.

You will see the coax filter design has a Q well over 4000 (four thousand) no this is not a misprint.

So I am not surprised that other techniques and constructions have trouble matching that Q and low loss.

Regards Len (builder of 30 coax filters).

8650. HF3 relay

Topic: 8650 Message: 8650

I have used the HF3 relays in a couple of past designs, but they seemed to become unavailable in 50-ohm versions. I discovered that Allied Electronics has them at a reasonable cost ($5.60 qty 1). They are non-stocked "Extended Range" items, but available with 8-10 day delays. In particular, they have the HF3-56 (12V non-latching) and HF3-96 (12V two-coil latching). These will operate down to 9V on only about 10 mA, and have excellent isolation.

If anyone bought the Signal Router board but never got the relays, you may want to check these out.

Sam W.

The Signal Router actually used the HF3-93 (5V) which Allied does not have, but they do have the HF3-92 (4.5 V) which would work just as well.

>
> I have used the HF3 relays in a couple of past designs, but they seemed to become unavailable in 50-ohm versions. I discovered that Allied Electronics has them at a reasonable cost ($5.60 qty 1). They are non-stocked "Extended Range" items, but available with 8-10 day delays. In particular, they have the HF3-56 (12V non-latching) and HF3-96 (12V two-coil latching). These will operate down to 9V on only about 10 mA, and have excellent isolation.

I have received the parts for the group buy of the input switch, etc. They will go out shortly, except a couple people will be delayed a few days because I under-counted the number of PE4251. (Apparently, I can only count to 500.) I also ended up with a couple of extra PCBs, so if anyone wants one (no other parts included), let me know. Cost is $18.

If you ordered but did not pay, please do so. I have received lots of payments, but have not tallied who paid and who didn't. I have been distracted because my mother, who lives with me, fell and broke her arm. My son will be handling the shipments.

Sam W.

Hi Sam, thank you for organising the Group Buy.

I am in Australia, as I understand you will be shipping a bulk order to Bill Maxwell (thanks Bill).

The cost for each Australian kit will be $46 is this correct?

Are you ready for to receive payment from us down under" and what Pay{al address can I send the money to?

Thank you

regards Gary VK2KYP

Jim,
I will put your name on the list of people to contact once I know that everyone got what they ordered, so I know the remaining boards are indeed extra.

(Also deleted your message so your address does not appear on Yahoo.)

8656. Using the MSA a Little Differently

Yahoo group: spectrumanalyzer (2011)

From: nealmartini
Topic: 8656 Message: 8656

I have been experimenting with something on my MSA that you all might be interested in trying. Very briefly, I have been using the output of the RFamp (before the final filter) to look at signals in the time domain. Additionally, I am using this same signal as a front end to a software defined radio to get very high resolution spectra and to listen to all kinds of radio signals.

Here are a few examples to demonstrate what I mean:

1. I attached a short wire antenna to the input of the MSA and activated an old remote control for a garage door opener. The remote uses OOSK modulation and the carrier is around 390 MHz. I connected the MSAs RFamp output to a low frequency scope and tuned the MSA to the 390 MHz center frequency. These two pictures show the hookup and scope output.

http://groups.yahoo.com/group/spectrumanalyzer/photos/album/995283679/pic/316786198/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc

http://groups.yahoo.com/group/spectrumanalyzer/photos/album/995283679/pic/316786198/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc

Here is another example of a 300 MHz AM modulated signal connected to the MSA input and the time domain viewing of the RFamp output on a scope.

http://groups.yahoo.com/group/spectrumanalyzer/photos/album/995283679/pic/316786198/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc

Incidentally, I have the RFamp output hooked up to a coaxial relay so I can switch the RFamp to either the MSA final filter or to an external connector that I hook to a scope.

2. Next I used the MSA RFamp output as a front end to a free downloadable FLEX RADIO software defined radio that runs in a PC. To use this software, you have to convert the RFamp signal to a baseband IQ signal so that it can be input to the PC via the sound card AtoD converter. I assembled an Ensemble II IQ converter (available online for $40)to generate the IQ signals. Basically, the Ensemble II takes the RFamps aprrox 10 MHz bandlimited signal and shifts it near DC. Once the IQ signal is sampled by the PC's sound card, you can use the FLEX RADIO software to get very high resolution spectra. You can also tune your MSA to radio signals and the FLEX RADIO will demodulate things so you can hear the radio broadcasts on your PC.

A few pictures to once again show what I am talking about. First here's an AM signal with 100Hz sine modulation shown in the FLEX RADIO.

http://groups.yahoo.com/group/spectrumanalyzer/photos/album/995283679/pic/316786198/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc

That 100 Hz line spacing would be very hard to produce in the MSA alone unless you had a very good final filter. Next here is an FM modulated signal, once again with a 100 Hz sine modulating signal.

http://groups.yahoo.com/group/spectrumanalyzer/photos/album/995283679/pic/316786198/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc

Finally, here is a 1350 KHz AM station being listened to on the FLEX RADIO with the MSA as the front end IF signal generator.

http://groups.yahoo.com/group/spectrumanalyzer/photos/album/995283679/pic/316786198/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc

Sorry this is so long, but there is alot here. There are more pictures in my photo album at the group site.

I hope you find this interesting.

8657. Using the MSA a Little Differently----Corrected Links

Yahoo group: spectrumanalyzer (2011)
Date: 2011-11-05 02:44:56 UTC
From: nealmartini
Topic: 8657 Message: 8657

I screwed up the links in my last posting-Sorry. Please use this posting to view photos.

I have been experimenting with something on my MSA that you all might be interested in trying. Very briefly, I have been using the output of the RFamp (before the final filter) to look at signals in the time domain. Additionally, I am using this same signal as a front end to a software defined radio to get very high resolution spectra and to listen to all kinds of radio signals.

Here are a few examples to demonstrate what I mean:

1. I attached a short wire antenna to the input of the MSA and activated an old remote control for a garage door opener. The remote uses OOSK modulation and the carrier is around 390 MHz. I connected the MSAs RFamp output to a low frequency scope and tuned the MSA to the 390 MHz center frequency. These two pictures show the hookup and scope output.

http://groups.yahoo.com/group/spectrumanalyzer/photos/album/995283679/pic/316786198/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc

See "Remote_Signal_Time_Domain" in photo album

Here is another example of a 300 MHz AM modulated signal connected to the MSA input and the time domain viewing of the RFamp output on a scope.

See "AM_Signal_on_Scope" in photo album

Incidentally, I have the RFamp output hooked up to a coaxial relay so I can switch the RFamp to either the MSA final filter or to an external connector that I hook to a scope.

2. Next I used the MSA RFamp output as a front end to a free downloadable FLEX RADIO software defined radio that runs in a PC. To use this software, you have to convert the RFamp signal to a baseband IQ signal so that it can be input to the PC via the sound card AtoD converter. I assembled an Ensemble II IQ converter (available online for $40)to generate the IQ signals. Basically, the Ensemble II takes the RFamps aprrox 10 MHz bandlimited signal and shifts it near DC. Once the IQ signal is sampled by the PC's sound card, you can use the FLEX RADIO software to get very high resolution spectra. You can also tune your MSA to radio signals and the FLEX RADIO will demodulate things so you can hear the radio broadcasts on your PC.

A few pictures to once again show what I am talking about. First here's an AM signal with 100Hz sine modulation shown in the FLEX RADIO.

See "AM_100Hz" in photo album

That 100 Hz line spacing would be very hard to produce in the MSA alone unless you had a very good final filter. Next here is an FM modulated signal, once again with a 100 Hz sine modulating signal.

See "ReFM_100Hz_1kHzDev" in photo album

Finally, here is a 1350 KHz AM station being listened to on the FLEX RADIO with the MSA as the front end IF signal generator.

See "ESPN_AM1350KHz_SDR" in photo album

Sorry this is so long, but there is alot here. There are more pictures in my photo album at the group site.

I hope you find this interesting.

Neal,
That is very slick. As far as switching goes, unless the Ensemble has significant junk signals headed back to the MSA, you don't need high isolation switching; you just don't want the RF amp loaded by both destinations at once. So you could use just about any switching IC or relay, or even PIN diodes. You could even use a resistor tap which would allow both to operate at once, though reducing the signal level slightly.

By the way, all your links actually point to the same photo, though it is easy to navigate from there.

Sam,

I used a coaxial relay I had because it came with SMA female connectors and was easy to plumb in without making a PCB. I added two push buttons on the front panel so I can easily switch back and forth.

Neal,
I'm all in favor of using what's at hand. I just didn't want anyone to get the impression that your nifty idea required an expensive or complicated switch.

I also looked at the Ensemble II. It's not all that complex but if you only need it for this purpose it looks like you could eliminate about half the components--especially filter components for other bands.

Sam W.

To use this software, you have to convert the RFamp signal to a baseband IQ signal so that it can be input to the PC via the sound card AtoD converter. I assembled an Ensemble II IQ converter (available online for $40)to generate the IQ signals. Basically, the Ensemble II takes the RFamps aprrox 10 MHz bandlimited signal and shifts it near DC. Once the IQ signal is sampled by the PC's sound card, you can use the FLEX RADIO software to get very high resolution spectra. You can also tune your MSA to radio signals and the FLEX RADIO will demodulate things so you can hear the radio broadcasts on your PC.

Sam,

I agree. Actually, you can eliminate all of the band pass filters. The cavity filter causes there to be a nice band limited signal at around 10 MHz and the Tayloe mixer does a complex spectrum down shift of this band limited signal. The Tayloe mixer is followed by a low pass filter to eliminate the other stuff that appears at the output of the MSA’s second mixer. The main reason to use this board is that it is pretty cheap and it already exists. If you eliminate all of the band pass filters, you only have to wind one very simple transformer that is used at the input to the Tayloe mixer.

Subject: [spectrumanalyzer] Re: Using the MSA a Little Differently

Neal,
I'm all in favor of using what's at hand. I just didn't want anyone to get the impression that your nifty idea required an expensive or complicated switch.

I also looked at the Ensemble II. It's not all that complex but if you only need it for this purpose it looks like you could eliminate about half the components--especially filter components for other bands.

Sam W.

As far as switching goes, unless the Ensemble has significant junk signals headed back to the MSA, you don't need high isolation switching; you just don't want the RF amp loaded by both destinations at once. So you could use just about any switching IC or relay, or even PIN diodes. You could even use a resistor tap which would allow both to operate at once, though reducing the signal level slightly.

Very briefly, I have been using the output of the RFamp (before the final filter) to look at signals in the time domain. Additionally, I am using this same signal as a front end to a software defined radio to get very high resolution spectra and to listen to all kinds of radio signals.

Does anyone have a current link for the schematics and pcb layouts for this set of boards. The links listed just give an error.

Thanks

Rex

Rex,
The schematics and PCB layouts of individual SLIM modules are here:
http://www.scottyspectrumanalyzer.com/slim.html

There are also some extras, such as the video filter, on my web site:
http://www.wetterlin.org/sam

Where did you run across the bad links?

Sam W.

Rex,
Sorry, I'm only half awake and misinterpreted your post as relating to the main SLIM boards, rather than that particular group buy. We sent the files to everyone who bought the boards; if they were posted here they then got deleted. I'll see if I can find a copy on my computer.
Sam W.

8667. Re: Board Group Buy

Yahoo group: spectrumanalyzer (2011)
Date: 2011-11-08 14:38:50 UTC
From: Sam
Topic: 7575 Message: 8667

Rex,
Checking through my emails I found that Jim Hontoria handled that group buy and I sent him the schematics for my boards, which are also on my web site. I do have a copy of the PCB and some schematics that I can send you, but hopefully Jim will have the complete collection, so I'll wait for his response. I think some of the boards, like the ceramic filters, don't have specific schematics. The ceramic filter is one or two filters with LC matches at input and output, so it is self-explanatory. In my photo albums I have some pictures of results with different filters.

8668. Input Switch Group Buy

Yahoo group: spectrumanalyzer (2011)
Date: 2011-11-08 16:16:07 UTC
From: Sam
Topic: 8668 Message: 8668

I have been notified that many US participants have received their boards, as well as the UK distributor for Europe. Other US participants don't need to notify me of receipt, but should notify me by email if they don't get their package by the end of the week.
Sam W.

Sam,

Do you remember which value you used to replace C25 100 pF of MXR-1. I remember from past emails that this was done to extend low end frequency response?!
Was there a corresponding change for MXR-2 C25 100 pF.

Jurgen

8670. Mixer 1 output cap

Yahoo group: spectrumanalyzer (2011)
Date: 2011-11-08 18:26:59 UTC
From: Sam
Topic: 7575 Message: 8670

This capacitor issue is only relevant to Mixer 1, and only if you want to implement the 2G band.

The issue has to do with the 2G band, where Mixer 1 needs to output 10.7 MHz rather than the usual 1+ GHz. Originally, I left the 100 pF resistor in place and put a relatively small attenuator in the diplexer, and it worked fine. Later, I replaced the 100 pF resistor--with 0.001 uF, I think--and intended to increase the diplexer attenuation, though I never got around to that. Still works fine. Ideally, the strength of the 10.7 MHz signal at the diplexer output in 2G should roughly equal that at the Mixer 2 output in 1G. That assures you get max range with 2G without overloading the IF2 amp and losing the high end.

8671. COAX FILTERS for sale

Yahoo group: spectrumanalyzer (2011)
Date: 2011-11-08 23:43:30 UTC
From: spyker49
Topic: 8671 Message: 8671

Hello Group.

I have had several requests asking if I had any more MSA coax filters for sale. No stock, so I plan to make another 10+.

Kits U$50. Complete and tested U$80.
Shipping from Australia typically $15 to US and Europe.
Target delivery date: January 2012.
PayPal money only at shipping time.

Please help reduce group ME TOO message clutter:
Please only reply to my email: redmond2@...

I have sold 30 coax filters so far.
See my group files for photos and kit build instructions.

Regards Len Spyker. redmond2@...

Has anyone developed a parts list for these PWB's that you'd be willing to share? Perhaps a text file similar in format to the parts lists for the SLIM's on Scotty's web site?

Thanks.

I don't have a parts list, but I should point out that other than the PE4251, the 1k and 100 ohm resistors, and 0.1 uF capacitors, there aren't that many parts.

Sam,

Where is the layout referenced in number 1 below?

Hi Sam,

I understand your point. It's helpful to me to have a list on which I can check off components as I put them on the board. Helps me keep organized. Thought I might find them already made :-)

Thanks.

8677. Forward/reverse switch . . . a couple of questions

Yahoo group: spectrumanalyzer (2011)
Date: 2011-11-11 02:38:10 UTC
From: Steve
Topic: 8677 Message: 8677

Hi Sam,

Looking at the .pcb file for the forward/reverse switch. Some resistors (such as R92, R93, R94) have the notation "Long--For use as jumper" in the Name field of the Component Properties screen. Other components have an "SEW" notation.

What does "Long--For use as jumper" mean? What does "SEW" mean?

Also, the schematic in the pdf should probably identify the PE4251's as U1, U2, U3 and U4 rather than just "U"?

Did you have in mind to provide +10VDC for this PWB from the control board?

Thanks.

Steve K8JQ

If someone needs data about NDK filters:

http://www.datasheetarchive.com/10P15DA-datasheet.html

I just bought a couple of 10p17d filters and used a 3uH inductor with a cap of 56p and a 60p trimmer to match the 910ohm/25p input. I still have a rippel of about 2db but the attenuation is good at 90db.
Are there any clever tricks to smooth the rippel?

See also the scan in files section....

Simon

Hi Steve,
Yes, the +10 comes from the control board. The U's should be numbered. "SEW" are my initials, to distinguish the standard ExpressPCB footprints from my modifications, and the jumper reference is for a slightly elongated 0805 footprint that makes it easier for a trace to run between the pads.

From: Sam
Topic: 8678 Message: 8680

That explains some things. First, they do have internal transformers. Second, the terminating impedance is 910 ohms || 25p, which I think is different from the eBay seller info. And while the data sheet graphs look pretty smooth, they do have a spec of 2 dB ripple.

Ordinarily, reducing the ripple is a matter of getting the impedance match right, but I think you're just lucky if you can get it much below the level of the spec. I think the ripple is caused by the fact that the various crystals are tuned to slightly different frequencies to cover the bandwidth.

Ripple seems to be a bigger problem for 7.5 kHz and 15 kHz crystal filters than for narrower ones. If the ripple forms a peak right in the middle, it's not so bad, but otherwise it is irritating. Ceramic filters can be a bit mis-shapen, but don't usually have much ripple, but start at about 30 kHz. To minimize ripple, I used a 2 kHz filter and then skipped to 30 kHz ceramic. (Plus the Amplifilter for very narrow RBW, and a 400 kHz ceramic.)

Sam W.

The four PE4251 on the F/R switch schematic should be numbered with the upper left one being U1, lower left U2, upper right U3 and lower right U4. Thus, U1 has resistors and capacitors labeled R1x and C1x, etc. They are numbered correctly on the PCB layout.

Hi Simon,
I notice that the 10p17d is not in their list. Assuming that it does have a terminating impedance of 910ohm/25p, then you want a total of 3.08 uH and 67.8 pfd. The 25 pfd of the filter must be included in the 67.8 pfd shunt capacitor. Therefore, you need to add only (67.8 - 25 =) 42.8 pf. with your 3 uH.

Hi Simon

I am using the NDK10P17D filter and have attached the filter plots for your reference.

I used toroids for the inductors and both took off turns and adjusted turn spacing to get an exact match. I also used 47p fixed caps and 60pf variables for the matching caps. Once I had got in the ball park the spacing of turns (inductance adjustment) became critical to optimise the ripple. The initial design value of the toroids was 3.5uH but I took off several turns so I guess they would be close to 3uH.

8685. Re: NDK filter data

Yahoo group: spectrumanalyzer (2011)
Date: 2011-11-12 18:14:28 UTC
From: sfcillari
Topic: 8678 Message: 8685

Hi all,

I followed rex's advice and replaced the inductors for some toroids. I measured them at about 3,3uh. This immediatly gave better results. After adding some windings and some fine tuning I got the ripple below 1db. See also the file 10p17d-tuned in the files section. I know this filter is not in the list but I think that I can conclude it has the same 910ohm/25pF impedance. Also the caps are very close too the calculated ones, 33pF+60pF trimmer 30% turned in.

This tuning requires a lot of patience and you really have to zoom in to iron out the ripples.....

Thanks for the replies,

Simon

It struck me as odd that the manufacturer includes internal transformers but leaves the impedance at such a high level. But I guess all they were trying to accomplish is to make all the filters have the same impedance, and it makes sense that your model would also have that impedance.

Yes, the tuning of these filters is very sensitive when you are trying to minimize the ripple.

I'll remind people of a potential problem soldering the canned filters. My first one I tried to solder all the way around to the PCB; I later concluded that if the filter sits down flat on the board you don't need 100% coverage. In any event, it is possible while soldering to melt the hermetic seal on the case, and heat the air inside so some of it bubbles out. Then when it cools it can suck the melted solder inside, possibly shorting out something inside (on mine it did short out). I discovered that there is a small hole in the can that is soldered over. Closing that hole must be the last thing in the manufacturing process, to avoid the sucking problem. The first thing you should do is remove the solder from the hole, then solder the case to the PCB, then close the hole.

Steve,
Up to 1 nF, NP0/COG is the way to go. I think you can even go to 10 nF, but they start to get more expensive. Above that, go with X7R until you get to large sizes (maybe 1 uF) and then X5R become a better deal.

8691. Coax Relays

Yahoo group: spectrumanalyzer (2011)
Date: 2011-11-14 00:24:36 UTC
From: Sam
Topic: 8691 Message: 8691

For anyone interested in coax relays for switching functions, such as the input switch or band switch, there are presently listed on eBay three items that have two 12V relays (they work fine at 10V) connected with coax, and an attenuator thrown in for good measure, now bid at $24.99 wit one day to go. Search for SMA relay and you will find them. If you want to see everything available, search for SMA relay and SMA switch.

The vast majority of available coax relays seem to be 24V or 28V. If you want to use that type, my 23V power supply board may provide the voltage you need. If not, a simple resistor change can increase the voltage (but you will also need higher voltage capacitors--35V vs. 25V).

From: Jurgen
Topic: 8694 Message: 8694

I build my cavity filter using a 1" copper tube on the outside. The rest is made of brass.

Here are my cavity filter test results:

Attenuation 5.8 dB
Bandwidth 2.9 MHz at 6dB
Center frequency 1013.3 MHz

How does this compare to the rest of you.

Thanks, Jurgen

Hi Jurgen. I've made a half dozen of these with all copper construction (One silver plated and no noticeable difference) Mine have measured about another 2 dB of attenuation, and about 0.8 MHz narrower in bandwidth. I would estimate yours to be more than adequate.

That sounds very good. You measured the bandwidth at 6 dB rather than 3 dB, which might make it hard to compare with others. In any event, the critical parameter is how much attenuation you get at 1013.3+21.4 MHz, because that is the image you are trying to reject. 90 dB below the peak is the target.

Topic: 8697 Message: 8697

How does the Mini-Circuits quote work, do I call the phone number stated on the quote (number in Brooklyn) and ask for the Amateur Spectrum Analyzer Kit KXMA-1+ ?

I just realised that this quote is incredible. When I ordered parts for my prototype at Mini-Circuits Europe I paid 140 EUR* (= 193 USD). That was without the transformer which was out of stock at the time and without the mixers, too.

(*: I paid 20 EUR freight charges and 20% VAT on top of it all = 140 EUR)

Right now I'm about to order 2 x ROS-2150, 1 x ROS-1500 and 5 x ADE-11X and already sit at 120 EUR (= 166 USD) without freight and tax. Made me wonder if I should call the Brooklyn number and ask.

For what it's worth, I just noticed that I may as well buy a lot of 25 of the mixers. The price is almost the same as for 5.

I will repeat the bandwidth measurement at 3dB.
I don't have a level meter to measure the attenuation at +21.4 MHz.
Will just have to see how it works with the rest of the circuit.

Thanks, Jurgen

That's the way I did it. I think there is a copy of the quote in the files section of our group. You should refer to the quote number. As I recall, when I did it, the quote had expired. I had them renew it, they had to run it through channels, but it was approved. This was a year or two ago, so I hope it is still good. If they say it has expired, ask if you can have it renewed, it worked for me.

Hi Jurgen,
 Once you have the cavity installed in the MSA, the attenuation test at 1013.3 + 21.4 MHz is very easy. You don't need any other equipment.

I would guess from the fact that you have decent loss and an OK bandwidth even when measured at 6 db, that your 3 dB bandwidth and the attenuation at +21.4 MHz will be good. As Scotty says, you can verify this when you get everything put together.

In July this year, I wrote to sales at minicircuits.com and asked for 'quote 5-QT-61201-A "AMATEUR SPECTRUM ANALYZER KIT" (tel: 612-599-1261)', and a couple of other components.

Mini-Circuits have also been happy to ship via USPS when I've asked, which saves a few dollars on freight.

8706. Re: Mini-Circuits quote

Yahoo group: spectrumanalyzer (2011)
Date: 2011-11-18 15:41:57 UTC
From: neganur
Topic: 8697 Message: 8706

Thanks for the replies. I received a quote from Mini-Circuits Europe today:

82.60 EUR for the whole kit plus 20 EUR delivery charge (excl. VAT).

The kit contains

1xROS-1500+
2x ROS-2150VW+
2x TC16-161TG2+
4xADE-11X+
10x ERA-33SM+

(I guess the additional transformer was a typo and I notified them)

I think this is an excellent offer compared to buying the components from the web store. I've asked for permission to publish the quote pdf file here in the Yahoo group once the quantities are updated.

Cheers for the help!

Chris

I haven't tried this place, but it looks interesting:

http://www.microstock-inc.com/newpage1.php

Look for UT-141. They have quite a variety of different coax types, including some nifty ones with very small diameters. You can buy small quantities but you have to ask for a quote, so I have no idea how the prices are.

Topic: 8672 Message: 8710

Hi!

I started populating the input switch and noticed that the PCB file doesn't match the schematic version (the PCB file version is two days older).

Additionally, R6 in the schematic is R5 on the PCB (1/4 W 100 Ohm). There is no R6 on the PCB.

The quality of the board is fantastic by the way, I was expecting the tinned solder mask-less PCB-Express style.

8713. 10.7 MHz noise filter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-11-19 13:19:02 UTC
From: marcolanie
Topic: 8713 Message: 8713

Hi

Reading the documentation of the MSA, I stumbled on this :

"The SLIM-CB-NV is designed with a Noise Filter Section. The noise filter is not required for any MSA configuration. All the components in that section can be omitted."

What was the historical reason of this filter ? and why is this element kept in the new version of the pcb ?

Tnks
Marc

Topic: 8713 Message: 8714

The noise filter never actually had anything to do with the control board; it was just too small to justify having its own SLIM board. I actually use it in my Expanded Log Detector, which consists of VGA-->Noise Filter-->Log Detector. It filters out much of the noise created or amplified by the VGA, giving a bit more dynamic range. (Actually, I then sacrifice some of that extra range by reducing the IF2 amp gain to a level I am more comfortable with). In order to use it I cut it off the control board and gave it an "in-line" configuration.

it was just too small to justify having its own SLIM board.
That's sounds logical

> I actually use it in my Expanded Log Detector, which consists of
VGA-->Noise Filter-->Log Detector.

Lost in the alphabet soup of the MSA: What is the VGA ? (first though, it
should be an input amplifier, but except the fixed IF amp, I can see nothing
else)

>It filters out much of the noise created or amplified by the VGA, giving a
bit more dynamic range.
>(Actually, I then sacrifice some of that extra range by reducing the IF2
amp gain to a level I am more comfortable with).

Added in the "to study" list.

> In order to use it I cut it off the control board and gave it an "in-line"
configuration.
I think I'd better print another pcb... playing surgery on the command board
seems a little bit tricky to me
Tnks again Sam

Hi Marc,
 Sam has it pretty close, but I'll elaborate. Originally, this area of the Control Board was just wasted space. So, I said to myself, "hmmmm, I hate wasted space so what to put there?". I reasoned that many builders would want to build (or buy) their own Final Crystal Filter(s). Since a fairly wide Final Filter would be a good option for one of the Final Filter Paths (one of four), I put the Ceramic Filter on the Control Board as one of the Paths. As it turned out, that particular ceramic filter (a single stage) did not have very good rejection at frequencies outside of its bandwidth. However, it is good enough for VNA purposes. Hence, it was left on the latest revision of the CB.
 I am pretty sure that the next revision of the CB will not have that filter area.

Thank you Scotty for those explanations.

In fact, I initially thought it was one of those filters, but the beginning of the “command board” chapter put me in trouble J

I already have 2 sets of filters. This will be the third one dedicated to the VNA, “just in case”. I’m pretty sure I have all the needed components in my junkbox, it won’t be a big deal if this filter will not be uses in the future.

Tnks again

Hi Marc,
Sam has it pretty close, but I'll elaborate. Originally, this area of the Control Board was just wasted space. So, I said to myself, "hmmmm, I hate wasted space so what to put there?". I reasoned that many builders would want to build (or buy) their own Final Crystal Filter(s). Since a fairly wide Final Filter would be a good option for one of the Final Filter Paths (one of four), I put the Ceramic Filter on the Control Board as one of the Paths. As it turned out, that particular ceramic filter (a single stage) did not have very good rejection at frequencies outside of its bandwidth. However, it is good enough for VNA purposes. Hence, it was left on the latest revision of the CB.
I am pretty sure that the next revision of the CB will not have that filter area.
Scotty

I should point out that while the single-stage ceramic filter does not make a great RBW filter, cascading two ceramics with nothing between them, but using the LC impedance match on the board input and output, makes a nice RBW filter for 30 kHz and up.

Hello. Try http://www.rfsupplier.com/ China.

For 402 .141 coax see Page link
http://www.rfsupplier.com/coaxial-cable-semi-rigid-rg402-feet-p-32.html

Note: the photo is wrong but the cable has an copper outer: $15 for 10 feet. Approx $3 per meter.

I have bought other SMA and BNC connector bits from them. They have been fine. Good English.

Regards Len Spyker

I noticed sparks during my first relay test. Shouldn't there be a diode over the relay coil?

My switch is basically ready. I ran out of 4.7uF ceramic capacitors though and the only other value I have in my SMD box are 2,2uF tantalum.

Chris,
I was hoping that the capacitors would handle that by slowing the turn-off, but I wasn't sure since I have no idea what the inductance of the coil is. Sounds like a diode might be a good idea.

2.2 uF caps are fine. This only needs to operate down to 100 kHz or so, and 2.2 uF will have fairly low impedance at that frequency.

8726. Input Switch

Yahoo group: spectrumanalyzer (2011)
Date: 2011-11-20 16:46:28 UTC
From: Sam
Topic: 8672 Message: 8726

I have largely completed the Input Switch. I tested the isolation with the necessary lids in place. A photo of the result is here:
<http://groups.yahoo.com/group/spectrumanalyzer/photos/album/252922278/pic/1534612461/view?picmode=&mode=tn&order=ordinal&start=1&count=20&dir=asc>

My goal was 90 dB isolation from 100 kHz to 1 GHz. I exceeded that everywhere except the bottom couple of kHz. Once above 300 kHz, the isolation exceeded 100 dB, except noise would occasionally make the graph spike above that level.

Sam W.

I have also dealt with these guys. They are eager to do business with anyone, and generally stock high quality Chinese RF products made to the same specifications as western goods. Just one word about contacting them. Their Chinese contact's English is pretty good, but unless you are careful what you write, there may be difficulties. Don't be ashamed to keep your sentences very basic, short, and to the point. I have found with my Uni students from China that this simple idea greatly maximises their understanding.
Slang, or lots of subordinate clauses will cause them serious problems, because the overall structure of Chinese languages is totally different from English!

8730. Input Switch

Yahoo group: spectrumanalyzer (2011)
Date: 2011-11-22 00:49:20 UTC
From: Sam
Topic: 8672 Message: 8730

I pose the following intellectual or experimental challenge relating to the Input Switch, which most likely applies to the Forward/Reverse switch (using the PE4251) as well.

The isolation of the switch is excellent from 1 MHz to 1 GHz. I haven't tested this exact switch at higher frequencies, but based on prototypes the isolation will decline, as one would expect, at higher frequencies.

The odd thing is that isolation apparently declines below 1 MHz. If you simply do a Transmission scan with the TG as input, it appears that leakage (crosstalk, if you prefer) increases as the frequency declines below 1 MHz, reaching about -80 dBm at 100 kHz. But I believe this actually has to do with some very high frequency components of the TG, and there is actually virtually no low frequency leakage. Consider these facts:

1. When tested at various phases of construction, the level of leakage was extremely sensitive to the amount of shielding. Normally, leakage at, say, 100 kHz, would not be "through the air", but would have to do with insufficient capacitor bypassing or some such thing.

2. If the TG is passed through a coaxial tee, with the third arm shorted, there should be virtually no 100 kHz signal surviving the tee. Yet the amount of apparent "leakage" remains constant.

3. If an external 100 kHz signal source is used, no leakage is apparent.

Here is the theory I pulled from my a**: There is some very high frequency leakage of signals with some low level AM or PM, which are somehow demodulated in the switches to create the apparent low frequency leakage. As an example, I know that op amps sometimes have the effect of demodulating signals beyond their frequency range.

One further experimental fact: using a MiniCircuits 700 MHz low pass filter on the TG has absolutely no effect once the board is properly shielded, but did have some effect before full shielding. I think this indicates that the frequencies of interest are too high for the filter to deal with. Consider that the filter is probably intended to be used on a thinner PCB than we use, and the grounding vias on a thinner board will be more effective.

If someone could figure out the cause, that would be appreciated. If someone could experimentally eliminate this effect, that would be even better.

8731. VHF Trans/Reflect Set

Yahoo group: spectrumanalyzer (2011)
Date: 2011-11-22 13:58:13 UTC
From: Sam
Topic: 8731 Message: 8731

Hi All,
A board labeled VHF Trans/Reflect Set was included in one of the PCB group buys. I have discovered two errors. First, there is provision on the board for ESD diode D1 on the T/R input, but that diode is missing from the schematic. ESD5V0D3 would work. Also, D2, the relay protection diode, is not properly placed on the schematic or board. It should be across the relay coil (pointing to + terminal), or pointing from the - coil terminal to the +10 supply.

I know of one person currently building this board. If anyone else has built it, let me know how it worked out.

From: sfcillari
Topic: 8732 Message: 8732

I just finished my rbw filter switch (which works perfect btw) and started to calibrate each path. When I got to the amplifilter (opa695) I hit a wall. To diagnose I connected a SG at the input of the filter and from +7db and up there was no increase at the output. So max. input level is about 7.5db. I then measured my IF amp output and it puts out +12.5db with -6db at the input of the msa. I believe that's about right. Is there a max. what the filter can handle? And what can I do to extend the range a bit?

Simon

From: Sam
Topic: 8732 Message: 8734

The op amp must be saturating. The MSA input level that causes saturation depends on losses in the mixers and cavity filter, and the gain of the IF2 amp.

Assuming you are using the 8V regulator, the simplest way to increase the upper end is to reduce the gain of the op amp. Sounds like you need to cut it in half (R5=560). This won't increase total range, because you will lose an equal amount of the low end. But you should probably adjust the op amp gain so the upper end of the amplifilter path approximately matches that of other paths, just for convenience.

As far as the max allowable power, the crystals in the amplifilter are probably no different from those in any other filter. For my taste, +12 dBm is too much power, but the range of the MSA depends in part on high IF2 amp gain, which means a lot of power through the filters at high input levels. That was part of my motivation with using the Expanded Log Detector, because it allowed me to get good range while decreasing the IF2 amp gain by about 10 dB. On the other hand, I haven't heard of anyone damaging a filter with the full IF2 amp gain.

Sam W.

Date: 2011-11-24 21:21:59 UTC
From: Jurgen
Topic: 8735 Message: 8735

My MSA is almost complete. Started testing.
Looking at spur's I found the following:

8.0264 MHz -73 dBm
9.3576 MHz -100 dBm
10.7 MHz -102 dBM
12.038 MHz -68 dBm
16.05 MHz -98 dBm
21.4 MHz -102 dBm

There may be more, but I was concentrating on peaks above -105 dBm.

All modules are fenced and properly mounted.
PLO's, Mixer's, Comp amp, IF amp, filter, VGA, are sealed.

Oscillator, phase detector, A/D converter fenced but still open.
All RF connections use UT141, solid copper tubing.
10.7 MHz section of DDS sealed, rest open.

I manually sealed the above modules with no effect.

How does this result compare to the rest of you.

Thanks, Jurgen

8736. SLIM PDM with Rev 0 pwb

Yahoo group: spectrumanalyzer (2011)
Date: 2011-11-24 22:59:54 UTC
From: Steve
Topic: 8736 Message: 8736

Scotty,

The phase detector module I constructed a couple of years ago uses a Rev 0 PWB and does not have the improvements for phase resolution or one-shot stability that were developed later.

I have another phase detector Rev 0 PWB with which I'd like to construct a second phase detector module with the improved operation -- I think that would make it a REV C SLIM. After I get the second one working, I plan to modify the first one for the same improvements.

Sadly, I have lost the printed copies I had of the parts list, schematic and text description related to the Rev 0 PWB. Seems to me I need those as a starting point. Are those documents still available? If they are out there on the web site, perhaps you could point me to them?

Thanks.

You have a smaller number of spurs than I do, but a couple of big ones. Your 12.038 MHz (8*LO1-8*LO2, I think) spur probably results from LO1 leaking through Mixer 1 and the cavity filter to Mixer 2, and mixing with LO2. Maybe you have high leakage of LO1 through Mixer 1. If you have a way to check the Mixer 1 output for LO2 content, it would be worth doing.

Thanks Sam,
That would mean Mixer 1 would be imbalanced? That would require an other SA which I don't have.
I wonder if the FFT from my scope would tell me anything. The levels are low, the internal scope noise would get into the way.

Hi Steve,
 I updated the PDM web page:
http://scottyspectrumanalyzer.com/slim_PDM.html
It now links the archived documents for what you need. Be sure to do a "refresh" in your browser to get the latest page.
Scotty

Scotty,

The phase detector module I constructed a couple of years ago uses a Rev

0 PWB and does not have the improvements for phase resolution or

one-shot stability that were developed later.

I have another phase detector Rev 0 PWB with which I'd like to construct

a second phase detector module with the improved operation -- I think

that would make it a REV C SLIM. After I get the second one working, I

plan to modify the first one for the same improvements.

Sadly, I have lost the printed copies I had of the parts list, schematic

and text description related to the Rev 0 PWB. Seems to me I need those

as a starting point. Are those documents still available? If they are

out there on the web site, perhaps you could point me to them?

Thanks.

Steve K8JQ

Jurgen,
If I have the mechanism right, the leakage through Mixer 1 would actually be pretty strong. LO1 would be 12.038 MHz above the cavity filter center, so it should be attenuated quite a bit before it gets to Mixer 2, and the level out of Mixer 1 could be -10 dBm or even higher.

Maybe the simplest thing would be to replace Mixer 1. Or maybe as a first step put an attenuator in the line from Mixer 1 to the cavity filter, to see what that does to your spurs. My guess it that this will reduce spurs for which (10.7 MHz-spur frequency) equals (10.7 MHz/N) for some small +/- integer N.

I scanned a new set of S1P data sets for that filter today, I'll combine them and upload once I'm home.

Hi Jurgen and All,
Spurs within the MSA (and any spectrum analyzer) are mathematically predictable. For the MSA, any time a combination of signals create 10.7 MHz (final I.F.) or 1013.3 MHz (1st I.F.) a potential spur will exist. Whether or not the spurs become problematic (visible on the graph) depends on the original design and the implementation of that design (filtering). The number of predictable spurs are related to the number of signals and the number of local oscillators and mixers. This is why my original design of the Spectrum Analyzer uses a dual conversion, rather than more multiple conversions like the Big Boys use. They create more spurs, then spend a lot of money on extra filtering to get rid of those spurs. (dumb)

The Verification MSA (in SA Mode) does not display any of your spurs except the one at 10.7 MHz (displayed as -112 dBm). They may be created in the MSA but they are below the noise floor at -120 dBm.

Sam guessed that the spur at 12.038 MHz is a product of the two PLO's (8*LO1-8*LO2). He is right on.

Here are the mathematics for known spurs.
(m*LO1 - n*LO2 = 10.7 MHz) or
(n*LO2 - m*LO1 = 10.7 MHz), where m and n are any whole numbers.
These formulas "assume" that the Master oscillator is "right on" at 64 MHz and the Final IF Filter is exactly 10.7 MHz. This dictates that LO1 will always be exactly 1013.3 MHz above the Commanded Frequency (where the spur shows up).

Here are some calculated known potential spurs:
Spur at 8.025 MHz: 4*LO2 - 4*LO1=10.7 MHz = 4*1024 - (4*1021.325) = 10.7
Spur at 9.3625 MHz: 8*LO2 - 8*LO1=10.7 MHz = 8*1024 - (8*1022.6625) = 10.7
Spur at 10.7 MHz : DDS 1 spurious (see below)
Spur at 12.0375 MHz : 8*LO1 - 8*LO2
Spur at 16.05 MHz : 2*LO1 - 2*LO2
Spur at 21.4 MHz : 1*LO1 - 1*LO2 (this is the image frequency that the cavity filter is designed to eliminate)
As you can see, these spurs are the ones you have, but are a tiny bit different in frequency. This is due to the fact that your Final Filter center is not exactly 10.700 MHz.

A little more on the DDS 1 spur at 10.7. If you expand your scale at this spur, you will probably find that the actual center frequency of the spur is the same frequency where DDS 1 is commanded to. Verify this by opening the Variables window and note the "dds1output = xx". Another method to verify that this spur is actually the DDS 1 frequency, halt the sweep, open the Sweep Parameters Window and click the Spur Test button. Continue the sweep and notice the spur has moved. The Spur Test changes the PLO 1 phase detector frequency, which changes the DDS 1 frequency.
The DDS 1 spur is created by the DDS 1 modulating the PLO 1 and creating sidebands. You can also see this spur by commanding the MSA Center Frequency to -10.7 MHz. Yes, this is allowed, although there is no such thing as a negative frequency. However, this commands

the PLO 1 to 1002.6 MHz. DDS 1 (10.7) creates an upper sideband (although small) at (1002.6 MHz + 10.7 MHz) = 1013.3 MHz. This sideband zips right through the Cavity Filter and mixes with PLO 2 in mixer 2, creating a signal at 10.7 MHz. Bingo, the spur.

Any time you see a spur in the MSA, expand the sweep to measure the 3 dB points of the spur. If the spur BW is less than the BW of your Final Resolution Filter, then you are dealing with a harmonic. For example, your Final Filter BW is 7 KHz. Your spur shows a BW to be 1.4 KHz. This is one fifth. So you are dealing with a 5th harmonic.

You have a smaller number of spurs than I do, but a couple of big ones. Your 12.038 MHz (8*LO1-8*LO2, I think) spur probably results from LO1 leaking through Mixer 1 and the cavity filter to Mixer 2, and mixing with LO2. Maybe you have high leakage of LO1 through Mixer 1. If you have a way to check the Mixer 1 output for LO2 content, it would be worth doing.

OK I managed to combine the touchstone 4-port file for the NDK 10P7D and you can find it in the files section.

http://groups.yahoo.com/group/spectrumanalyzer/files/Crystal%20Filters%20RBW/NDK%2010P7D/

I will try to replace the old data of the other filters as time permits. Sam pointed out that I had not properly set the frequency resolution the network analyser I used to record the files. As a result, I had 1600 points worth of data but only with a kHz resolution and therefore quantisation errors. The new data has a resolution of 1 Hz and should be just fine.

There's both data for a matched filter (0.4 dB ripple) and the filter plain, with nothing but coax connected to take the measurements.

EDIT:

I just uploaded the file and looked at its contents. There are still some frequency duplicates. The RF network analyser I used is an HP 8714ET. It's supposed to provide touchstone data but no frequency should appear twice according to Sam. I believe you can still use the file to find a match with the SMA software, but importing it into RFSim99 may crash the programme.

Hope this helps

Chris

It appears that the common element in all of Jurgen's spurs, except that at 10.7 MHz, is that they depend on LO1 (or certain harmonics) passing through Mixer 1 and the cavity filter. If it is actually LO1 leakage, I would have expected the spurs to be stronger where LO1 is closest to 1013.3 MHz, meaning LO1 would pass most easily through the cavity filter. But that is not the case, making me suspect that what is really leaking is the second and/or fourth harmonic of LO1. The fourth harmonic in particular might have an easy time passing through the cavity filter, and would explain why the strongest spurs involve multiples of 4 and 8.

Perhaps a simple low pass filter at the cavity filter input or output would solve the problem. Like the Minicircuits LFCN-1000.

It is also possible that the amount of leakage through Mixer 1 is sensitive to the LO level. Jurgen, if your LO1 is very strong, you might consider reducing it 3 dB to see what happens.

Jurgen,
If you want to try the filter approach, the Minicircuits VLFX-825 SMA filter would be a simple and reliable way to go, though it would cost you $40. It would completely zap all LO1 harmonics to and beyond 20 GHz. Of course, if leakage of the LO1 fundamental is the problem (which I suspect it isn't), this won't help.
Sam W.

Your 12.038 MHz (8*LO1-8*LO2, I think) spur probably results from LO1 leaking through Mixer 1 and the cavity filter to Mixer 2, and mixing with LO2. Maybe you have high leakage of LO1 through Mixer 1. If you have a way to check the Mixer 1 output for LO2 content, it would be worth doing.

8748. Re: [spectrumanalyzer] Re: Spurs

Yahoo group: spectrumanalyzer (2011)
Date: 2011-11-25 20:48:48 UTC
From: Jurgen
Topic: 8735 Message: 8748

I do remember running an FFT using my scope on the PLO1 and PLO2
outputs. They had a large amount of second and third harmonic content.
I remember mentioning this in a post. They seem to have been within the
manufacturers specifications.
Need to repeat the measurements.
I will put an attenuator in series with the cavity filter output and see
if that validates the assumptions.

Thanks for all your responses, Jurgen

Sam,
I am a bit lost, we want the cavity filter to pass 1013.3 MHz.
The VLFX-825 is a 825 MHz low pass filter and will attenuate 1013.3 MHz.
What am I missing?
Jurgen

Thanks Chris,

Very low ripple, nice.
What do the skirts look like down to about -100 dBm.
I am looking for a filter with clean skirts to as low as possible level.

Jurgen

I don't remember if I have any better pictures but I hope this one (the attachment) will do.

I use a home-brew PCB without proper plated through holes etc and the shield/fence is double-sided FR4 and copper tape. Pretty sure a proper board could improve the noise floor but this is the best filter my prototype has.

If I am correct it looks like the somewhere greater than 90 db.
There is the beginning of a lobe on the right hand side.

There are 3 filters 10P17D for sale on ebay.
I wonder what the difference is between the two, yours is a 10P7D.
I could not find any data sheets.

the difference is the bandwidth. The NDK10P17D has a bandwidth of 17 kHz.

The VLFX-825 will only attenuate slightly over 1 dB at 1013.3 MHz. Minicircuits doesn't name their filters using the 3 dB corner frequency.

From: Sam
Topic: 8735 Message: 8755

Yes, the harmonic content of the PLO signals is large. And of course by being used as the LO in a mixer there will be even more generated. The real question is how much of the harmonics escape into the mixer output.
Sam W.

Someone from the UK is selling NDK10P7D on ebay, in case you missed them. Stock is 100 pieces or so.

Chris

8757. Re: Spurs

Yahoo group: spectrumanalyzer (2011)
Date: 2011-11-26 19:32:29 UTC
From: Sam
Topic: 8735 Message: 8757

Jurgen,
If you want to watch the N*LO1-N*LO2 spurs while taking some action to get rid of them, and you don't want the really slow scans that result from using a huge number of steps, here is the way to set up the scan:

1. Set your desired RBW path and look in Show Variables to see the Real Final IF frequency.

2. Use the Real Final IF as the center of the scan and as the scan width.

3. Use 840 steps.

This will make the step size IF2/840. An integral number of such steps can equal IF2/2, IF2/3,... or IF2/8. All the spurs of interest will differ from IF2 by one of those values (+ or -) and therefore you will hit all the spurs on the head.

This won't hit the 21.4 MHz spur. If you want that one, double the scan width and double the number of steps to 1680.

Jurgen, in your case the only relevant multiples seem to be 2, 4 and 8, and possibly 7 so you could use a mere 56 steps (the least common multiple of those numbers) instead of 840.

Sam W.

Thanks for letting me know. I did buy one. I also bought 3 10P17D from
someone in Australia. I probably only need two at the most.
Need to buy the components for the matching networks.
All of this plus my spurs are going to keep me busy for a while.
Jurgen

8759. Re: Spurs (N*LO1-N*LO2)

Yahoo group: spectrumanalyzer (2011)
Date: 2011-11-26 22:40:02 UTC
From: Sam
Topic: 8735 Message: 8759

After some experimentation, I have revised my method of searching for the N*LO1-N*LO2 (or N*LO2-N*LO1) spurs:

1. Set the center and span to the final filter center frequency that you specified in the list of paths. Don't use a path with RBW less than 1 kHz unless you limit the scan to a small number of points (see (5) below).

2. You can use the 840 steps I suggested before. But when looking for spurs you may have to watch several scans to see whether spikes at a given frequency come and go. For this purpose it is more convenient to have a fast scan with clearly separated scan points.

3. To pick up the spurs from a given set of multiples N1, N2, ...N3, you need a number of steps equal to the least common multiple of those values, and if that comes out an odd number, you have to double it to make it even (in order that your center frequency is actually a scan point).

4. To pick up all multiples 2 through 8 requires steps equal to their least common multiple, which is 840. But that gives scan points crowded together.

5. It is best to break the scan into two parts. For example, using 3*4*5=60 steps will pick up spurs involving multiples 2, 3, 4, 5 and 6, and a separate scan of 7*8=56 steps will pick up multiples of 2, 4, 7 and 8 (which all divide 56 evenly). Since the second scan picks up multiples of 2 and 4, they can be dropped from the first scan, giving only 3*5=15 steps, but you have to double that to make it even.

6. With scans of a small number of steps, the scan is fast and well separated and it is easy tell whether individual points are stable or varying around a measurable value, in which case they are spurs, or whether they appear and disappear, in which case they are noise (though low level invisible spurs are still possible at those points).

7. Graphing as a histogram works best visually when you have such a small number of points.

Hi, don't know if any one on here has need of a Texscan RCB-3 Return Loss Bridge type RCB-3 + N type Mismatches. All included in a nice wooden box.

I am still having a clear out and discovered this item buried in a my pile of must do something with items!

I have it on eBay as item number 220902630263

Thanks and 73 Clive GW0PPO

Hi,

I'm using a 5v supply for the opamp and switching to 8v gave me an extra 3db. I'll try lowering the gain because it's already amplfying more then the insertion loss of the crystals.

The op amp must be saturating. The MSA input level that causes saturation depends on losses in the mixers and cavity filter, and the gain of the IF2 amp.

Assuming you are using the 8V regulator, the simplest way to increase the upper end is to reduce the gain of the op amp. Sounds like you need to cut it in half (R5=560). This won't increase total range, because you will lose an equal amount of the low end. But you should probably adjust the op amp gain so the upper end of the amplifilter path approximately matches that of other paths, just for convenience.

As far as the max allowable power, the crystals in the amplifilter are probably no different from those in any other filter. For my taste, +12 dBm is too much power, but the range of the MSA depends in part on high IF2 amp gain, which means a lot of power through the filters at high input levels. That was part of my motivation with using the Expanded Log Detector, because it allowed me to get good range while decreasing the IF2 amp gain by about 10 dB. On the other hand, I haven't heard of anyone damaging a filter with the full IF2 amp gain.

To diagnose I connected a SG at the input of the filter and from +7db and up there was no increase at the output. So max. input level is about 7.5db. I then measured my IF amp output and it puts out +12.5db with -6db at the input of the msa. I believe that's about right. Is there a max. what the filter can handle? And what can I do to extend the range a bit?

Per the schematic, the 5V regulator is only for using the OPA356 op amp, which is rail-to-rail or close to it. Also, remember that with an op amp the overall voltage gain gets cut in half by the 50 ohm output resistor. The op amp is really there for buffering, not for gain. It's probably a good idea to reduce the gain so the insertion loss of the amplifilter is comparable to your other RBW filters, or at least so that there is some actual insertion loss.

8764. LO1 Leakage Spurs

Yahoo group: spectrumanalyzer (2011)
Date: 2011-11-29 01:01:51 UTC
From: Sam
Topic: 8764 Message: 8764

Hi All,
I have posted a document discussing the spurs that Jurgen has reported, and that others might experience at various levels:

<http://groups.yahoo.com/group/spectrumanalyzer/files/SamW%20Files/LO1_Leakage_Spurs.pdf>

I call these LO1 Leakage Spurs. Perhaps Mixer 1 Leakage Spurs would be a better term (because LO1 can also leak in other ways), and some might prefer the term crosstalk rather than leakage.

The document discusses the underlying mechanism, and identifies the specific frequencies involved (elaborating on Scotty's comments). We have not yet resolved the source of Jurgen's unusually high spurs, but the current suspect is the tuning of the cavity filter.

In short, if you have a spur at frequency Fspur, your final IF frequency is IF2, and Fspur differs from IF2 by IF2/N for some reasonably small integer N, then you have one of these spurs. They are all at or below 2*IF2. If you zoom in on the spur, you will see that, while a normal signal shows up with a width approximately equal to your RBW, the spur will have a width of RBW/N.

I have also created a folder called SamW Files, and moved most of my files there, to reduce file sprawl. Some file links from older messages thus may not work. I did not move the Minicircuits quotes or the current beta of the MSA software.

Sam W.

From: spyker49
Topic: 8766 Message: 8766

Hello Group
So far I have orders for 12 Coax filters for delivery in January 2012, thank you very much.
One order has a custom frequency!
Fully assembled and tested U$80 + U$15 overseas post from Perth Australia.
I aim to build 15-20 units so there is some stock.
A friend with a machine shop is helping me with the cutting of the 160 copper pipe sections. Before this run I cut the other 240 sections by hand.
Please reply only to redmond2@iinet.net.au
Regards Len Spyker

Topic: 8736 Message: 8769

Scotty,

I continue to plod along on my second phase detector SLIM and would appreciate your advice to ensure I'm headed in the right direction. My goal is to have a PDM with the latest available modifications.

Keeping in mind that I have a Rev 0 PWB, here's what I plan to do:
1. Construct a Rev A phase detector module based upon SLIM-PDM Rev A, SKSLIM-PDM Rev A, PWB-PDM Rev 0 and PLSLIM-PDM Rev A.
2. Implement the four MOD's detailed at the end of the current web page in the section entitled "Updated 10-21-08 Modification of the SLIM-PDM-revA".

Do those steps sound right?

Given that I have a "blank" PWB, is there merit in building the Rev A PDM and testing it in my working MSA prior to implementing the four MOD's? Or would it make for easier construction to incorporate the four MOD's into the first-pass build?

Is there an "official" nomenclature for the Rev A PDM SLIM that has the four MOD's? Is there a rev level? Or is it just known as "Rev A with the four MOD's"? :-)

Is the performance of the "Rev A with the four MOD's" equivalent to the Rev C PDM SLIM?

Thanks.

Hi Steve,
 Since your board is blank, I would build it up with the mods. rather than build a RevA and then modify it. It is easiest to slice those 4 traces on an empty board. The SLIM-RevA (PWB-Rev0) with mods is just as accurate as RevC. There was no special name given to the RevA with mods, other than just to say "my RevA has all the mods". When you finish, I would mark the bottom of the pwb, "PDM-RevA", "modified", and the date you did it. Years from now you won't have to scratch your head or lift the lid to verify what it is.

Scotty,

I continue to plod along on my second phase detector SLIM and would

appreciate your advice to ensure I'm headed in the right direction. My

goal is to have a PDM with the latest available modifications.

Keeping in mind that I have a Rev 0 PWB, here's what I plan to do:

1. Construct a Rev A phase detector module based upon SLIM-PDM Rev A,

SKSLIM-PDM Rev A, PWB-PDM Rev 0 and PLSLIM-PDM Rev A.

2. Implement the four MOD's detailed at the end of the current web page

in the section entitled "Updated 10-21-08 Modification of the

SLIM-PDM-revA".

Do those steps sound right?

Given that I have a "blank" PWB, is there merit in building the Rev A

PDM and testing it in my working MSA prior to implementing the four

MOD's? Or would it make for easier construction to incorporate the four

MOD's into the first-pass build?

Is there an "official" nomenclature for the Rev A PDM SLIM that has the

four MOD's? Is there a rev level? Or is it just known as "Rev A with the

four MOD's"? :-)

Is the performance of the "Rev A with the four MOD's" equivalent to the

Rev C PDM SLIM?

Thanks.

Thanks for the advice. And I've learned over the years to label everything!

One more question if I may: The web page for the PDM, near the end, has a section that begins "MOD 4: Allows the Phase Detector IC (U5) to be powered by the SLIM-ADC module." The web page for the ADC, near the beginning, has a section with whose opening sentence reads "This optional modification allows the SLIM-ADC-16 to be powered directly by the Phase Detector Module's regulated +5 volts." So it appears that either module can power the other. Does it matter which powers which? Is there a preference?

The important thing is that both the output flip-flop of the PDM and ADC have the same power supply, so the max PDM output voltage matches what the ADC expects. As I recall, I ended up powering the two modules in the opposite way that Scotty did, but I think I had to cut a trace on one of the modules to avoid the two regulators directly battling.

Hi Steve,
 Sam is right, it really doesn't matter which scheme you use. By theory, powering the final stage of the PDM from the ADC module should give more accuracy to the MSA (Mod 4). However, powering the ADC from the PDM is an easier modification. I have done both and can see no difference in accuracy. I may just delete Mod 4 to simplify things.
 The "no mod" scheme is to power the PDM and ADC independently from the 10v on the Control Board. Here, I did see a significant difference, due to the modules having different temperature changes. The error over a large temperature change was a little over 1 degree in phase error.
Scotty

8774. 1013 MHz SAW Filter Alternative for the MSA Cavity Filter

Yahoo group: spectrumanalyzer (2011)
Date: 2011-12-06 04:27:08 UTC
From: nealmartini
Topic: 8774 Message: 8774

All,

Let me start out with the bottom line. With a lot of help from Scotty, I put together a working prototype of a 1013 MHz SAW based filter that can be used in place of the Cavity Filter that is currently in the MSA. The resulting filter has 100 dB of ultimate rejection, >90 dB of rejection at the MSA second mixer's image frequency (around 1034 MHz), and has near 0 dB insertion loss (contains an amplifier). The PCB footprint is equivalent to one SLIM size board (1.2" x 1.2").

A few months ago I started looking at building another MSA and wanted to reduce its size as much as possible. The Cavity Filter is obviously a big factor in the MSA's size. I decided to try and duplicate the Cavity Filter's function utilizing a SAW based design. I found a source for a SAW from a company in England (Gooledge) that looked like it would be perfect for the job. I put together a design and PCB layout and approached Scotty with the idea. Scotty altered my design and layouts, and we iterated the design through a couple of cycles. The resulting performance we obtained turned out to be excellent.

I created a file folder called "1013 MHz SAW Filter"

http://groups.yahoo.com/group/spectrumanalyzer/files/1013%20MHz%20SAW%20Filter%20/

on the group page for you all to look at. The folder contains various frequency responses, pictures of the PCB, and construction stage photos. I also included a data sheet for the SAW that was used. Basically, the design consists of three cascaded SAWs, a few PADs and an ERA-33 amplifier. If you look at the group file, you will get a good idea of the approach and performance.

I am curious if there would be any interest out there for putting together some sort of group buy for this filter. A group buy would be for the SAWs (three required/filter-I paid $5.75/each ordering in small quantity), a PCB (>$5.00/each), plus shipping. The quantity we order will obviously drive the SAW cost. The rest of the parts needed to complete the assembly (caps, resistors, connectors,etc.) are very similar to the MSA's current IF ERA-33SM based amplifier. If there is enough interest, I would be willing to facilitate the group buy of the SAWs and PCBs.

Before we formally begin a group buy, those of you out there with interest please post a response so we can get an idea of what quantities we may be talking about. BTW, Scotty is considering adding this to the formal SLIM list. He is working on putting the PCB layout, schematic and parts lists in the form consistent with what he uses for SLIMs.

Neal

Excellent idea, I'd take at least two.

I finally managed to finish assembling my cavity filter yesterday evening and I'm in the process of documenting it. Sam gave me some excellent advice regarding the hair-pin decouplers a few days ago.

Hi All,
I think Neal has hit a home run. For potential MSA builders who have been afraid of tackling the Cavity Filter, this is a great alternative.
I was a bit skeptical at first. These SAW filters are the smallest I have ever seen (3 mm square) and I thought that assembly might be a problem. However, Neal says they reflow quite nicely and they also are easy to install with a standard small tip iron.
Please take a good look at Neal's photos during his assembly. His soldering and fencing are not great. And, with construction of items this small, I'm not surprised. I don't say this to step on Neal's toes, but rather, to bring up the point that "perfect" construction is not critical to get great results.
I do believe this will make a good SLIM design. The company that distributes these SAWs have a long list of other SAWs with the same footprint. So, utilizing this SLIM with different SAWs would be pretty handy for other projects. (example, Filter and Amplifier for a frequency multiplier scheme).
I have added two more of Neal's plotted test results to his previously named file section. One is a sweep of the Single SAW Filter and Amplifier. This shows a really good response of the single filter. This plot response is extremely close to what the Vendor specifies. What is important (to me, anyway) is that other SAW filters from this Vendor can probably be trusted to be specified correctly.
The other addition is the response of two SAWs cascaded (the smaller module). In other projects, the ultimate rejection for two SAWs might be sufficient without adding the SAW/Amplifier module.
I will be creating a Web page for the SLIM design and will release a full set of documentation.
Scotty

Attachments: 1 described; binary payloads are missing from this source WARC

All-I added a rough schematic of the filter in the folder for those that requested it.

Sam-I asked for a quote and placed the order for the SAWs. I don’t know what their internal inventory situation was. It took about two weeks to receive parts.

Greg-Sorry for the big files. I will use .gif as you suggest in the future. Thanks

Scotty-I am looking around to find a class in “soldering and fencing”

Neal
count me for a 1013 Mhz filter set.

Please add me in the group buy for three sets.

Tnx and Best Regards,

Chuck w8dux

Neal,
count me for two filter sets.

I don't even need them, have several cavity ones lying around, but my obsessive compulsive just hit a high note.

Neal,

I am interested in two filter sets.

Thanks

Subject: [spectrumanalyzer] 1013 MHz SAW Filter Alternative for the MSA Cavity Filter

All,

Let me start out with the bottom line. With a lot of help from Scotty, I put together a working prototype of a 1013 MHz SAW based filter that can be used in place of the Cavity Filter that is currently in the MSA. The resulting filter has 100 dB of ultimate rejection, >90 dB of rejection at the MSA second mixer's image frequency (around 1034 MHz), and has near 0 dB insertion loss (contains an amplifier). The PCB footprint is equivalent to one SLIM size board (1.2" x 1.2").

A few months ago I started looking at building another MSA and wanted to reduce its size as much as possible. The Cavity Filter is obviously a big factor in the MSA's size. I decided to try and duplicate the Cavity Filter's function utilizing a SAW based design. I found a source for a SAW from a company in England (Gooledge) that looked like it would be perfect for the job. I put together a design and PCB layout and approached Scotty with the idea. Scotty altered my design and layouts, and we iterated the design through a couple of cycles. The resulting performance we obtained turned out to be excellent.

I created a file folder called "1013 MHz SAW Filter"

http://groups.yahoo.com/group/spectrumanalyzer/files/1013%20MHz%20SAW%20Filter%20/

on the group page for you all to look at. The folder contains various frequency responses, pictures of the PCB, and construction stage photos. I also included a data sheet for the SAW that was used. Basically, the design consists of three cascaded SAWs, a few PADs and an ERA-33 amplifier. If you

look at the group file, you will get a good idea of the approach and performance.

I am curious if there would be any interest out there for putting together some sort of group buy for this filter. A group buy would be for the SAWs (three required/filter-I paid $5.75/each ordering in small quantity), a PCB (>$5.00/each), plus shipping. The quantity we order will obviously drive the SAW cost. The rest of the parts needed to complete the assembly (caps, resistors, connectors,etc.) are very similar to the MSA's current IF ERA-33SM based amplifier. If there is enough interest, I would be willing to facilitate the group buy of the SAWs and PCBs.

Before we formally begin a group buy, those of you out there with interest please post a response so we can get an idea of what quantities we may be talking about. BTW, Scotty is considering adding this to the formal SLIM list. He is working on putting the PCB layout, schematic and parts lists in the form consistent with what he uses for SLIMs.

Neal

Please include me for two units.

Thanks, Jurgen
